

## 21 **Abstract**

22 CFST T-joints consisting of a concrete-filled circular chord and a circular hollow  
23 section brace have been used in CFST trussed arch bridges. The stress concentration  
24 factors (SCFs) of CFST T-joints have been found to be much lower than those of  
25 circular hollow section (CHS) T-joints in the existing researches. At present, no  
26 parametric formulae have been proposed for SCFs determination for fatigue design of  
27 CFST T-joints. In this study, three-dimensional finite element (FE) models of the  
28 existing experiments for CFST T-joints were developed to determine the SCFs  
29 distribution at the chord-brace intersection under axial force in the brace. After  
30 confirming the validity of the FE models by the comparison of calculated SCFs with  
31 existing experimental results, they were provided for the parametric analysis to reveal  
32 the influence of four non-dimensional parameters, i.e. diameter ratio ( $\beta$ ), diameter to  
33 thickness ratio of chord ( $2\gamma$ ), thickness ratio ( $\tau$ ) and relative chord length ( $\alpha$ ), on SCFs  
34 of CFST T-joints. In total, 212 FE models with different parameters were analyzed  
35 under tensile and compressive axial forces. Based on the results of parametric  
36 analysis, a series of parametric formulae to calculate the SCFs was proposed for  
37 CFST T-joints referring to those for CHS T-joints. The SCFs determined by the  
38 formulae showed good agreements with FE analysis results.

39 **Key words:** CFST T-joints; Stress concentration factors; Hot spot stress; Fatigue;  
40 Finite element analysis; Parametric formulae.

## 42 **1 Introduction**

43       After the construction of the first CFST arch bridge, Wangcang East River  
44 Bridge in 1990, CFST trussed arch bridges have become very popular, and more than  
45 400 CFST arch bridges have been constructed in the last 25 years in China. Their  
46 arch ribs can be categorized into solid type and trussed type, and the latter accounts  
47 for about 38% [1]. The trussed arch ribs consist of concrete-filled circular chords and  
48 circular hollow braces generally connected with full penetration butt welds to form  
49 CFST joint, including T-joints, Y-joints, K-joints, N-joints and so on. The filled-in  
50 concrete delays buckling of steel tube, and improves its compressive strength and  
51 ductility. However, the intersection with full penetration butt welds in CFST joint can  
52 be the weak part in the whole structure since the axial stiffness of brace is much  
53 larger than the radial stiffness of chord tube, which leads to high stress concentration  
54 around the chord-brace intersection. In fact, the fatigue cracks seriously damaging the  
55 structural safety were found in the chord-brace intersection of a half-through CFST  
56 trussed arch bridge in China [2].

57       Fatigue life of tubular joints is commonly related to the SCFs at the weld toes of  
58 the chord-brace intersection. So far, many studies to formulate the SCFs of various  
59 types of CHS joints as functions of main structural parameters have been carried out  
60 by many researchers, such as Kuang et al. [3], Efthymiou and Durkin [4], Hellier et al.  
61 [5], Smedley and Fisher [6], Mashiri et al. [7] and Zhao et al. [8]. The developed SCF  
62 formulae for the chord-brace intersection have been extensively adopted in many

63 current national and international design codes for fatigue evaluation of the joints by  
64 hot spot stress (HSS) method [9-13]. However, there has not been many studies on  
65 fatigue of CFST joints to date and the appropriate SCFs formulae for them are rarely  
66 found in literatures and design codes. In addition, the Chinese code (JTG/T  
67 D65-06-2015) only gives allowable value of nominal stress amplitude for the fatigue  
68 checking calculation of CFST joints [14].

69 Tong et al. [15] experimentally investigated the SCFs of CFST K-joints, and  
70 revealed that they have more uniform distribution and obviously smaller values than  
71 CHS K-joints. Mashiri [16] found that the SCFs of CFST T-joint are generally lower  
72 than those of CHS T-joint under in-plane bending in the brace. By means of static test  
73 for CFST T-joints, Wang [17, 19], Chen [18, 20] and Xu [21] determined the SCFs  
74 and compared them with those estimated by some existing formulae for CHS T-joints.

75 Very limited studies have been conducted on the SCF formulae of CFST T-joints.  
76 Wang [19] and Chen [20] considered that filled-concrete can improve the local  
77 stiffness at the chord-brace intersection of CFST T-joints and its effect can be  
78 equivalent to the increase of chord wall thickness. They proposed a determination  
79 method of the equivalent chord wall thickness to use the existing SCF formulae for  
80 CHS T-joints. However, the SCFs calculated by the method were generally larger  
81 than the experimental investigation, especially under axial compressive force in the  
82 brace. In addition, the validity range of diameter to thickness ratio of chord  $2\gamma$  in the  
83 method does not much its practical range of bridge structures. Furthermore, the  
84 influence of relative chord length  $\alpha$  on SCFs is not investigated.

85 In this study, FE models to evaluate the SCFs of CFST T-joint (see **Fig. 1**) were  
86 developed first. After validating them by the comparison with existing experimental  
87 results in [18, 20, 21], they were provided for parametric analysis. Then, based on the  
88 parametric analysis results, SCF formulae of CFST T-joints subjected to axial force in  
89 the brace were proposed as functions of key non-dimensional geometric parameters.  
90 Finally, the accuracy of the formulae was verified by comparing the SCFs obtained  
91 by the formulae and FE analysis.

## 92 **2 Validation of FE modelling**

### 93 *2.1 Brief summary of experimental studies on SCFs of CFST T-joints*

94 The experiments to determine SCFs for CFST T-joints with different geometric  
95 parameters were carried out and published in [17, 18, 20, 21]. The loading methods  
96 are shown in **Fig. 2**. One end of chord was fixed, and another end was pin-rolled in  
97 [18, 20]. Both ends of chord were fixed in [21], and pin-rolled in [17]. The specimens  
98 were designed as shown in **Table 1** to evaluate the influence of different  
99 dimensionless geometric parameters, i.e. diameter ratio  $\beta$  ( $= d/D$ ), diameter to  
100 thickness ratio of chord  $2\gamma$  ( $= D/T$ ) and thickness ratio  $\tau$  ( $= t/T$ ). The axial  
101 compressive or tensile force was applied to the hollow brace, which was fully welded  
102 at a right angle to the continuous concrete-filled chord. The static tests within elastic  
103 range were performed to obtain the HSS and the SCFs at weld toe of the specimens  
104 were determined.

## 105 *2.2 FE models*

106 The general purpose FE analysis software MSC.Marc was applied for the  
107 numerical investigation on SCF distribution of CFST T-joint under axial force in the  
108 brace. Since the measured HSS was much lower than yield stress in the experiment,  
109 linear elastic analysis in terms of material properties was conducted. The values of  
110 Young's modulus and Poisson's ratio were set to those shown in the article, as  
111 summarized in **Table 2**.

112 If the steel tube was modeled by shell element, it becomes difficult to model the  
113 weld bead and make good contact behavior between steel tube and concrete.  
114 Therefore, the linear full-integration eight-node hexahedron solid element was used  
115 for whole model, i.e. steel tube, concrete and weld bead. The leg sizes of weld bead at  
116 the brace and chord were set to  $t$  and  $0.5t$  ( $t$ : the wall thickness of brace), respectively,  
117 according to AWS code [10].

118 Since the mesh size needs to be small enough to get the accurate HSS, fine mesh  
119 should be used around the intersection. The mesh dimensions of  $0.5T$  to  $0.5t$  around  
120 focused areas were suggested for solid element [22]. The influence of mesh size  
121 around the chord-brace intersection on the SCFs is examined in 2.4.

122 The behavior of the interface between chord tube and concrete can be simulated  
123 by "Glue" or "Touch" function. "Glue" function assumes that contact bodies tie  
124 together without any relative displacements. "Touch" function allows contact bodies  
125 to touch and separate each other in normal direction, and slide with the friction  
126 behavior in tangential direction. The function to be used is determined in 2.5. The

127 whole FE model and local mesh around the intersection are shown in **Fig. 3**.

### 128 *2.3 HSS calculation*

129 The HSS around the chord-brace intersection was obtained numerically by linear  
130 extrapolation. The positions of two nodes for HSS calculation is shown in **Fig. 4** and  
131 **Table 3** [13]. The positions are arbitrarily determined in this region since the stress  
132 distribution is almost linear. In this study, the positions of 1st and 2nd nodes are  
133 approximately  $0.4T$  (but  $\geq 4$  mm) and  $1.0T$  away from the weld toe, respectively. The  
134 SCF is generally defined as the ratio of the HSS at the joint to the nominal stress in  
135 the member due to the basic member load causing this HSS [13]. Therefore, the  
136 nominal stress of the brace subjected to the axial force  $F$  was determined using a  
137 simple formula ( $\sigma_n = F/A$ ), where  $A$  is the cross-sectional area of the brace [17],  
138 which was used for SCF calculation in this study.

### 139 *2.4 Mesh size around chord-brace intersection*

140 In order to determine the mesh size around the intersection, its influence on  
141 SCFs was examined. The three mesh conditions listed in **Table 4** were considered to  
142 calculate the SCFs of CFCHS-4 specimen in [17]. The influence of mesh size on  
143 SCFs for location CC under tensile or compressive axial force in the brace is shown  
144 in **Fig. 5**. It shows that the SCFs gradually increase as the mesh size decreases.  
145 Considering the balance between calculation accuracy and efficiency, the mesh size  
146 of approximately 2 mm was adopted in the parametric analysis.

## 147 *2.5 Modeling of chord tube-concrete interface*

148 The friction coefficient ( $\mu$ ) between concrete and steel is from 0.2 to 0.6 in  
149 general [23]. The SCFs at the chord crown under tensile force in the brace obtained  
150 by FE analysis with “Glue” and “Touch” functions assuming different friction  
151 coefficient in the range are compared with the test result of T-300-4 specimen [24] in  
152 **Fig. 6**. It shows that the SCFs calculated with “Glue” function are much lower than  
153 test result. However, the SCFs calculated with “Touch” function show good  
154 agreement with the test result and friction coefficient has almost no influence on the  
155 SCFs. Therefore, “Touch” function with  $\mu = 0.3$  was arbitrarily adopted in this study.

156 The relative deformations between chord and concrete around the chord-brace  
157 intersection are shown in **Fig. 7**. It is confirmed that total cross-section of chord and  
158 concrete bears the axial force in the brace with “Glue” function, while employing  
159 “Touch” function leads to separation between chord and filled-concrete around  
160 intersection.

## 161 *2.6 Validation of the FE models*

162 **Fig. 8** shows a comparison of SCF distributions between FE analysis ( $SCF_{FEA}$ )  
163 and experiment ( $SCF_{Test}$ ) for CFCHS-4 specimen in [17]. The developed FE model  
164 reproduces not only similar distribution but also similar magnitudes in SCFs.

165 Comparisons between the  $SCF_{FEA}$  and  $SCF_{Test}$  in four locations (chord saddle CS,  
166 chord crown CC, brace saddle BS and brace crown BC) and the maximum SCFs  
167 among four locations in each specimen are shown in **Fig. 9** for all specimens. The

168 averages of  $SCF_{FEA}$  to  $SCF_{Test}$  ratio of the locations CS, CC, BS, BC and maximum  
169 SCFs location under tensile condition are 1.22, 0.95, 0.98, 0.79 and 0.97, respectively,  
170 and those under compressive condition are 0.96, 0.86, 0.86, 0.68 and 0.86,  
171 respectively. The  $SCF_{FEA}$  under tensile condition shows good agreement with the  
172  $SCF_{Test}$  although they show larger deviation under compressive condition. The  
173 external surface of filled-concrete might have much smaller Young's modulus than  
174 design value in the actual specimen due to imperfect construction such as incomplete  
175 filling and generation of laitance. It would cause the larger measured SCFs than the  
176 calculated SCFs in FE model under compressive condition. However, it would hardly  
177 affect the measured SCFs under tensile condition because of the separation between  
178 chord tube and concrete around the intersection. Consequently, such difference in  
179 deviation has occurred between tensile and compressive conditions.

180 In order to examine the influence of such imperfect construction on the SCFs,  
181 CFCHS-4 specimen was analyzed assuming 0.5 and 0.1 times of Young's modulus  
182 for the concrete elements up to approximately 10mm deep from the surface. **Table 5**  
183 summarizes the results. It shows the great and slight influences of imperfect  
184 construction on the SCFs under compressive and tensile conditions, respectively. In  
185 other words, larger SCFs can be obtained under compression in the test if there is  
186 such imperfect construction.

187 The deviation of  $SCF_{FEA}$  at location BC is large not only under compressive  
188 condition, but also under tensile condition compared with the other locations.  
189 Therefore, it can be thought that some fabrication errors exist in the brace. For

190 example, its plate thickness or diameter is less than design value and the angle  
191 between chord and brace is not  $90^\circ$ .

192 Based on the above discussions, it can be concluded that the developed FE  
193 models can predict the SCF distribution of CFST T-joint under axial loading in the  
194 brace with sufficient accuracy.

### 195 **3 Parametric analysis on SCFs**

#### 196 *3.1 FE models*

197 Based on the SCF formulae of CHS T-joints [13] and the existing experimental  
198 results [17, 18], the diameter ratio  $\beta$  ( $= d/D$ ), diameter to thickness ratio of chord  $2\gamma$   
199 ( $= D/T$ ), thickness ratio  $\tau$  ( $= t/T$ ) and relative chord length  $\alpha$  ( $= 2L/D$ ) are considered  
200 to be the key parameters for the determination of SCFs of CFST T-joints. Therefore,  
201 these four parameters were changed within the practical ranges shown in **Table 6** in  
202 the parametric analysis. The practical ranges were determined based on the geometric  
203 parameters statistics of CFST K-joint for 119 CFST trussed arch bridges in China  
204 [24].

205 The geometric dimensions of standard FE model, which was set referring to the  
206 common dimensions of CFST trussed arch bridges [1], are shown in **Table 7**. Two  
207 hundred and twelve FE models with different combination of geometric parameters  
208 were prepared and analyzed.

209 In general, the braces mainly bear axial forces and the chords bear axial

210 compressive force and in-plane bending in the arch ribs of CFST trussed arch bridges.  
211 Therefore, CFST T-joints generally subject to axial force in the brace and axial force  
212 and in-plane bending in the chord, as shown in **Table 8**. In this study, only axial force  
213 in the brace was used as the loading condition to carry out the parametric analysis. In  
214 addition, the pinned chord ends and free brace end were employed in the FE models.

215 Young's modulus of steel tube and concrete were set to  $2.05 \times 10^5$  MPa and  
216  $3.45 \times 10^4$  MPa, and their Poisson's ratio were set to 0.3 and 0.2, respectively. Wang  
217 [17] experimentally presented that the effect of concrete strength on the SCFs of  
218 CFST T-joints was not significant, even can be neglected. Since concrete with the  
219 strength between 30 and 60 MPa has been applied to the arch ribs of CFST arch  
220 bridges in China [1], the concrete of 50 MPa grade was assumed for the  
221 determination of Young's modulus of concrete [25].

## 222 *3.2 Results and discussions*

### 223 *3.2.1 Influence of diameter ratio $\beta$*

224 The influences of  $\beta$  on SCFs are illustrated in **Fig. 10**.

225 For the location CS (**Fig. 10 (a)**), the  $SCF_{CS}$  decreases as the value of  $\beta$  increases  
226 under tensile force. However, under compressive force, it increases for larger values  
227 of  $\beta$ .

228 For the location CC (**Fig. 10 (b)**), the  $SCF_{CC}$  increases as the value of  $\beta$  increases  
229 under tensile and compressive force.

230 For the location BS (**Fig. 10 (c)**), the  $SCF_{BS}$  decreases as the value of  $\beta$  increases

231 from 0.3 to 0.5 under tensile force, but it increases as the value of  $\beta$  increases from  
232 0.5 to 0.6. Moreover, it increases as the value of  $\beta$  increases under compressive force.

233 For the location BC (**Fig. 10 (d)**), the  $SCF_{BC}$  decreases as the value of  $\beta$   
234 increases under tensile force. However, the influence of  $\beta$  on  $SCF_{BC}$  is not significant  
235 under compressive force.

### 236 *3.2.2 Influence of diameter to thickness ratio of chord $2\gamma$*

237 The influences of  $2\gamma$  on SCFs are illustrated in **Fig. 11**.

238 For the location CS (**Fig. 11(a)**), the  $SCF_{CS}$  increases as the value of  $2\gamma$  increases  
239 under tensile force. However, it decreases as the value of  $2\gamma$  increases under  
240 compressive force.

241 For the location CC (**Fig. 11(b)**), the  $SCF_{CC}$  increases as the value of  $2\gamma$   
242 increases under tensile force. However, it decreases as the value of  $\beta$  increases under  
243 compressive force.

244 For the location BS (**Fig. 11(c)**), the  $SCF_{BS}$  increases as the value of  $2\gamma$  increases  
245 under tensile force. Moreover, it increases as the value of  $2\gamma$  increases from 40 to 50  
246 under compressive force, but it decreases as the value of  $2\gamma$  increases from 50 to 80.

247 For the location BC (**Fig. 11(d)**), the  $SCF_{BC}$  decreases as the value of  $2\gamma$   
248 increases under tensile and compressive force.

### 249 *3.2.3 Influence of thickness ratio $\tau$*

250 The influences of  $\tau$  on SCFs are illustrated in **Fig. 12**.

251 For the location CS (**Fig. 12(a)**), the  $SCF_{CS}$  increases as the value of  $\tau$  increases

252 under tensile and compressive force.

253 For the location CC (**Fig. 12(b)**), the  $SCF_{CC}$  increases as the value  $\tau$  increases  
254 under tensile and compressive force.

255 For the location BS (**Fig. 12(c)**), the  $SCF_{BS}$  increases as the value of  $\tau$  increases  
256 under tensile force. Moreover, it increases as the value of  $\tau$  increases from 0.4 to 0.7  
257 under compressive force, but it decreases as the value of  $\tau$  increases from 0.7 to 1.0.

258 For the location BC (**Fig. 12(d)**), the  $SCF_{BC}$  increases as the value of  $\tau$  increases  
259 from 0.4 to 0.5 under tensile force, but it decreases as the value of  $\tau$  increases from  
260 0.5 to 1.0. In addition, it increases as the value of  $\tau$  increases under compressive  
261 force.

#### 262 *3.2.4 Influence of relative chord length $\alpha$*

263 The influences of  $\alpha$  on SCFs are illustrated in **Fig. 13**.

264 For the location CS (**Fig. 13(a)**), the influence of  $\alpha$  on the  $SCF_{CS}$  can be  
265 neglected under tensile force. In addition, the influence is also not significant under  
266 compressive force.

267 For the location CC (**Fig. 13(b)**), the  $SCF_{CC}$  increases as the value of  $\alpha$  increases  
268 under tensile and compressive forces.

269 For the location BS (**Fig. 13(c)**), the influence of  $\alpha$  on the  $SCF_{BS}$  can be  
270 neglected under tensile force. Moreover, the influences of  $\alpha$  is not significant under  
271 compressive force.

272 For the location BC (**Fig. 13(d)**), the influence of  $\alpha$  on the  $SCF_{BC}$  can be

273 neglected under tensile and compressive forces.

### 274 *3.2.5 Discussions*

275 By comparing the SCFs caused by tensile force with those caused by  
276 compressive force shown in **Figs. 10-13**, it can be noticed that the former is generally  
277 much larger than the latter. Since the adhesion between the steel and concrete was not  
278 strong, the inner wall of chord tube around the intersection tended to separate from  
279 the surface of filled-concrete when the brace was subjected to tensile force.  
280 Consequently, the out-of-plane bending deformation of the chord tube around the  
281 intersection became larger, which induced higher HSS under tensile force than under  
282 compressive force. In addition, the influence of  $\tau$  on SCFs is much larger than that of  
283  $\beta$ ,  $2\gamma$  and  $\alpha$  for all four locations in most cases.

284 By comparing the  $SCF_{CS}$  with  $SCF_{CC}$ , it can be also noticed that the  $SCF_{CS}$  are  
285 larger under tensile force, while the  $SCF_{CC}$  are larger under compressive force in most  
286 cases. It indicates that the maximum SCFs in the chord generally occur at the saddle  
287 (CS) and crown (CC) under tensile and compressive force, respectively. Meanwhile,  
288 the maximum SCFs of CHS T-joints generally occur at location CS, regardless of  
289 whether the axial force applied to the brace is compression or tension [17]. The  
290 mechanical behavior around the intersection of CFST T-joints under tensile force is  
291 considered to be similar to that of CHS T-joints since the separation between chord  
292 tube and filled-concrete can occur in CFST T-joint. In contrast, the filled-concrete  
293 greatly increases the stiffness of CFST T-joint against compressive force in the brace

294 and makes the stress distribution around the intersection more uniform. Furthermore,  
295 the position of the maximum SCFs changed from the saddle (CS) to crown (CC).

296 By comparing the  $SCF_{BS}$  with  $SCF_{BC}$ , it can be noticed that the  $SCF_{BS}$  are  
297 generally larger under tensile force, while the magnitudes of  $SCF_{BS}$  and  $SCF_{BC}$  are  
298 similar under compressive force. In other words, the maximum SCFs in the brace  
299 occur at the saddle (BS) under tensile force in general. However, they can occur at the  
300 saddle (BS) or crown (BC) under compressive force. The difference of maximum  
301 SCF location in the brace can be explained similarly to the above discussions.

## 302 **4 SCF formulae for CFST T-joints**

### 303 *4.1 Formulation*

304 Based on the results of parametric analysis as well as the SCF formulae given in  
305 the CIDECT Design Guide [13] for CHS T-joints subjected to axial force in the brace,  
306 the SCF formulae at locations CS and CC under tensile or compressive force can be  
307 expressed as **Eqs. (1)** and **(2)**, respectively. Those at locations BS and BC under  
308 tensile and compressive force can be expressed as **Eqs. (3)** and **(4)**, respectively.

309 The axial loading in the brace results in a bending moment in the chord. The  
310 bending moment is the main cause of the stress at location CC, and it changes with  
311 chord length which can be represented by  $\alpha$ . Therefore, the influence of  $\alpha$  on SCFs at  
312 location CC needs to be considered. Referring to [26], the last term corresponding to  
313 the SCF at location CC due to global bending is introduced in **Eq. (2)**. The direction  
314 of stress caused by the bending moment in the chord is the longitudinal direction

315 along the chord tube and perpendicular to the weld toe at location CC, while parallel  
 316 to the weld toe at location CS. Therefore, the influence of  $\alpha$  on SCFs at location CS is  
 317 not considered in **Eq. (1)**.

$$\text{SCF}_{\text{CS}} = A_{\text{CS}} \cdot \gamma^{B_{\text{CS}}} \cdot \tau^{C_{\text{CS}}} \cdot [D_{\text{CS}} + E_{\text{CS}} \cdot (\beta + F_{\text{CS}})^2] \quad (1)$$

$$\text{SCF}_{\text{CC}} = A_{\text{CC}} \cdot \gamma^{B_{\text{CC}}} \cdot \tau^{C_{\text{CC}}} \cdot [D_{\text{CC}} + E_{\text{CC}} \cdot (\beta + F_{\text{CC}})^2] + \frac{M_{\text{Chord}}}{W_e \sigma_n} \quad (2)$$

$$\text{SCF}_{\text{BS}} = A_{\text{BS}} \cdot \gamma^{B_{\text{BS}}} \cdot \tau^{C_{\text{BS}}} \cdot [D_{\text{BS}} + E_{\text{BS}} \cdot (\beta + F_{\text{BS}})^2] \quad (\text{tension}) \quad (3a)$$

$$= A_{\text{BS}} \cdot \gamma^{B_{\text{BS}}} \cdot \beta^{C_{\text{BS}}} \cdot [D_{\text{BS}} + E_{\text{BS}} \cdot (\tau + F_{\text{BS}})^2] \quad (\text{compression}) \quad (3b)$$

$$\text{SCF}_{\text{BC}} = A_{\text{BC}} \cdot \gamma^{B_{\text{BC}}} \cdot \beta^{C_{\text{BC}}} \cdot [D_{\text{BC}} + E_{\text{BC}} \cdot (\tau + F_{\text{BC}})^2] \quad (\text{tension}) \quad (4a)$$

$$= A_{\text{BC}} \cdot \gamma^{B_{\text{BC}}} \cdot \tau^{C_{\text{BC}}} \cdot \beta^{D_{\text{BC}}} \quad (\text{compression}) \quad (4b)$$

318 where, the constants  $A_{\text{CS}}$  to  $F_{\text{CS}}$ ,  $A_{\text{CC}}$  to  $F_{\text{CC}}$ ,  $A_{\text{BS}}$  to  $F_{\text{BS}}$  and  $A_{\text{BC}}$  to  $F_{\text{BC}}$  would be  
 319 determined by multiple regression analysis.  $M_{\text{Chord}}$  is the global bending moment in  
 320 the chord around the intersection,  $W_e$  is the section modulus for equivalent steel tube  
 321 section, and  $\sigma_n$  is the nominal stress in the brace.  
 322

323 Assuming a small wall thickness compared with the diameter of brace, the  
 324 relation between the force  $F$  and the nominal stress in the brace ( $\sigma_n$ ) is derived as  
 325 follows.

$$326 \quad F = \pi d t \sigma_n \quad (5)$$

327 The flexural stiffness  $EI$  of concrete-filled chord is determined according to the  
 328 **Eq. (6)** [27].

$$329 \quad EI = E_c I_c + E_s I_s \quad (6)$$

330 where,  $E_c$  and  $E_s$ ,  $I_c$  and  $I_s$  are the Young's moduli and moments of inertia of  
 331 filled-concrete and steel tube, respectively.

332 The moment of inertia of steel tube and filled-concrete are calculated by **Eqs. (7)**  
 333 and **(8)**, respectively.

$$334 \quad I_s = \frac{\pi[D^4 - (D - 2T)^4]}{64} \quad (7)$$

$$335 \quad I_c = \frac{\pi(D - 2T)^4}{64} \quad (8)$$

336 From **Eqs. (6)-(8)**, the wall thickness  $T_e$  of the equivalent steel tube section is  
 337 derived as follows.

$$338 \quad T_e = \frac{D - (D - 2T) \cdot \sqrt[4]{\frac{m-1}{m}}}{2} \quad (9)$$

$$339 \quad m = \frac{E_s}{E_c} \quad (10)$$

340 Consequently, the section modulus for equivalent steel tube section  $W_e$  is  
 341 obtained as follows.

$$342 \quad W_e = \frac{\pi D^3}{32} (1 - n^4) \quad (11)$$

$$343 \quad n = \frac{D - 2T_e}{D} \quad (12)$$

344 According to the results of the multiple regression analysis, the formulae for  
 345 determining SCFs in the chord and brace of CFST T-joints under axial force in the  
 346 brace are given as follows,

347 Location CS

$$\text{SCF}_{\text{CS}} = 2.351\gamma^{0.39}\tau^{1.03}[0.818 + 1.254(\beta - 0.878)^2] \quad (\text{tension}) \quad (13a)$$

$$= 6.767\gamma^{-0.482}\tau^{0.79}[0.984 + 1.255(\beta - 0.198)^2] \quad (\text{compression}) \quad (13b)$$

348 Location CC

$$\text{SCF}_{\text{CC}} = 1.401\gamma^{0.365}\tau^{0.916}[1.028 + 0.883(\beta - 0.29)^2] + \frac{M_{\text{Chord}}}{W_e\sigma_n} \quad (\text{tension}) \quad (14a)$$

$$= 37.077\gamma^{-1.096}\tau^{0.895}[1.122 - 0.095(\beta + 0.274)^2] + \frac{M_{\text{Chord}}}{W_e\sigma_n} \quad (\text{compression}) \quad (14b)$$

349 Location BS

$$\text{SCF}_{\text{BS}} = 0.636\gamma^{0.308}\tau^{0.28}[2.751 + 8.645(\beta - 0.531)^2] \quad (\text{tension}) \quad (15a)$$

$$= 0.989\gamma^{-0.044}\beta^{0.316}[2.942 - 0.638(\tau - 0.759)^2] \quad (\text{compression}) \quad (15b)$$

350 Location BC

$$\text{SCF}_{\text{BC}} = 1.122\gamma^{-0.228}\beta^{-0.317}[3.154 - 3.121(\tau - 0.519)^2] \quad (\text{tension}) \quad (16a)$$

$$= 6.025\gamma^{-0.329}\tau^{0.326}\beta^{-0.007} \quad (\text{compression}) \quad (16b)$$

351 The validity ranges of the proposed parametric formulae in **Eqs. (13)-(16)** are  
352  $0.3 \leq \beta \leq 0.6$ ,  $40 \leq 2\gamma \leq 80$ ,  $0.4 \leq \tau \leq 1.0$  and  $12 \leq \alpha \leq 20$  since the validity of the  
353 formulae has been confirmed only for those ranges.

#### 354 4.2 Accuracy verification

355 The SCFs obtained by the proposed formulae,  $\text{SCF}_{\text{FOR}}$ , were compared with  
356 those by FEA,  $\text{SCF}_{\text{FEA}}$ , for all locations to verify the accuracy of the formulae. The  
357 comparisons under axial tensile force and compressive force are shown in **Figs.**  
358 **14(a)-(d)** and **Figs. 14(e)-(h)**, respectively. They include the statistical values of the  
359 ratio of  $\text{SCF}_{\text{FOR}}$  to  $\text{SCF}_{\text{FEA}}$ ,  $\text{SCF}_{\text{FOR}}/\text{SCF}_{\text{FEA}}$ , as well. The graphs show the good  
360 agreement between  $\text{SCF}_{\text{FOR}}$  and  $\text{SCF}_{\text{FEA}}$  in general. The mean values of  
361  $\text{SCF}_{\text{FOR}}/\text{SCF}_{\text{FEA}}$  are very close to 1.0 for all locations, and the corresponding  
362 coefficients of variance (COV) are relatively small.

363 However, conspicuous disagreements and different trends are observed at

364 locations CS and BS under compressive axial force. In order to examine the reason,  
365 **Figs. 14(e) and (g)** are divided into three graphs by  $\alpha$ -value, respectively, as shown in  
366 **Fig. 15**. Then, most different trends disappear. It indicates that the different trends are  
367 mainly caused by ignoring the influence of  $\alpha$ -value in the developed formulae for  
368 locations CS and BS. Although the accuracy can be improved by considering the  
369 influence of  $\alpha$ -value, the authors do not think that it is necessary due to much smaller  
370 SCFs than those at the same locations under tension.

371 Therefore, it can be concluded that the proposed SCFs formulae have sufficient  
372 accuracy and reliability for CFST T-joints under axial force in the brace.

373

## 374 **5 Conclusions**

375 This study focuses on the SCFs of CFST T-joints under axial force in the brace.  
376 The validity of the developed FE models was evaluated by comparison with the  
377 existing experimental results. Parametric analysis was conducted by using the  
378 validated FE model to reveal the effects of the key four non-dimensional geometric  
379 parameters ( $\beta$ ,  $2\gamma$ ,  $\tau$  and  $\alpha$ ) on the SCFs. Based on the numerical results from 424 FE  
380 analyses, a series of parametric formulae were proposed to determine the SCFs of  
381 CFST T-joints under axial force in the brace. The main conclusions are summarized  
382 as follows.

383 (1) The developed three-dimensional FE models can determine the HSS at the  
384 chord-brace intersection under axial force in the brace with sufficient accuracy.

385 (2) The influence of non-dimensional geometric parameters ( $\beta$ ,  $2\gamma$ ,  $\tau$  and  $\alpha$ ) on  
386 SCFs of CFST T-joints under axial force in the brace can be summarized as shown in  
387 **Table 9**. Moreover, the influence of  $\tau$  on the SCFs is much larger than that of  $\beta$ ,  $2\gamma$   
388 and  $\alpha$  for all four locations in most cases.

389 (3) The SCFs in the chord caused by axial tensile force are much larger than  
390 those under compression. The maximum SCFs in the chord generally occur at  
391 locations CS and CC under axial tensile and compressive force, respectively. The  
392 maximum SCFs in the brace occur at location BS under axial tensile force in general.  
393 However, they can occur at locations BS or BC under axial compressive force.

394 (4) Using multiple regression analysis, parametric formulae to determine the  
395 SCFs for CFST T-joints under axial force in the brace were developed. Sufficient  
396 accuracy and reliability of the proposed formulae were demonstrated by comparison  
397 with FE analysis results.

398 As described in 4.1, the validity range of each parameter for the formulae is set  
399 to the same as that in the parametric analysis. Examination of the applicability of the  
400 parametric formulae for wider range of the parameters can be one of the future work.
