# 30 Running title

31 Accurate detection of ESBL by MBT STAR-BL

### 32 Abstract

- 33 The MALDI Biotyper Selective Testing of Antibiotic Resistance–β-Lactamase (MBT
- 34 STAR-BL) assay, which analyzes bacterial induced hydrolysis of cefotaxime using
- 35 MALDI-TOF MS, correctly identified 100.0% of extended-spectrum  $\beta$ -lactamase
- 36 (ESBL)-producing *Enterobacteriaceae* as positive and 94.7% of non-ESBL producers
- as negative in 80 strains tested.
- 38
- 39 Key words: MALDI-TOF MS, ESBL, Antibiotic resistance

**Text** 

41	Extended-spectrum $\beta$ -lactamase (ESBL)-producing <i>Enterobacteriaceae</i> represent a
42	significant public health concern. A previous study from Japan reported that ESBL-
43	producing Escherichia coli and Klebsiella pneumoniae are spreading, accounting for
44	23.0% of E. coli and 10.7% of K. pneumoniae infections in 2014-2015 (Takesue et al.,
45	2017).
46	We recently reported the reliable performance of the MALDI Biotyper Selective
47	Testing of Antibiotic Resistance– $\beta$ -Lactamase (MBT STAR-BL) assay, which analyzes
48	bacterial induced hydrolysis of $\beta$ -lactam antibiotics using matrix-assisted laser
49	desorption ionization-time-of-flight mass spectrometry (MALDI-TOF MS), for
50	detecting IMP metallo-β-lactamase (MBL) activity in <i>Enterobacteriaceae</i> (Kawamoto et
51	al., 2018). In the present study, we also investigated the utility of the MBT STAR-BL
52	assay for the detection of ESBL activity in Enterobacteriaceae.
53	We used Enterobacteriaceae (E. coli and K. pneumoniae) clinically isolated at the
54	Nagasaki University Hospital between January 2011 and May 2016. MICs were
55	determined using a BD Phoenix Automated Microbiology System (BD Diagnostics).
56	ESBL production was also detected using the BD Phoenix system (Leverstein-van Hall
57	et al., 2002; Sanguinetti et al., 2003). The presence of ESBL genes was evaluated by

58	PCR. PCR amplification of ESBL genes (variants of CTX-M-group 1, including CTX-
59	M-1, CTX-M-3, and CTX-M-15; variants of CTX-M–group 2, including CTX-M-2;
60	variants of CTX-M-group 9, including CTX-M-9 and CTX-M-14; TEM variants,
61	including TEM-1 and TEM-2; and SHV variants, including SHV-1) was performed
62	using previously described primers (Dallenne et al., 2010) under the following
63	conditions: 10 min at 95°C, 30 cycles consisting of 40 s at 95°C, 40 s at 60°C, 1 min at
64	72°C, and 7 min at 72°C for the final extension for ESBL genes, as described previously
65	(Higashino et al., 2017). Analysis of cefotaxime hydrolysis using the MBT STAR-BL
66	assay (including calibration) was performed according to the manufacturer's
67	instructions, as described previously (Kawamoto et al., 2018). Three to five individual
68	bacterial colonies were randomly collected using a $1-\mu L$ inoculation loop, suspended in
69	50 $\mu L$ of solution (10 mM NH4CO3, 10 $\mu g/mL$ ZnCl2 [pH 8]) containing 0.5 mg/mL of
70	cefotaxime, and incubated at 37°C for 2 h according to the manufacturer's instructions.
71	Signal peak intensity was used to calculate the logRQ value (a measure of
72	hydrolysis efficiency), which was the logarithm of the ratio of the summed intensity of
73	the hydrolyzed form (molecular peaks of $[M_{hydrolyzed/deacetyl} + H]^+$ at 414 $m/z$ and
74	$[M_{hydrolyzed/decarboxylated/deacetyl} + H]^+$ at 370 $m/z$ ) to the summed intensity of the non-
75	hydrolyzed form (peaks of $[M + H]^+$ at 456 $m/z$ , the sodium adducts $[M + Na]^+$ at 478

76	$m/z$ and $[M + 2Na]^+$ at 500 $m/z$ , and $[M_{deacetyl} + H]^+$ at 396 $m/z$ ). Higher logRQ values
77	indicated a higher degree of antibiotic hydrolysis (Kawamoto et al., 2018; Oviano and
78	Bou, 2017). The 95% confidence intervals (CIs) for sensitivity and specificity were
79	calculated using R statistical software (https://cran.ism.ac.jp/) (Kosai et al., 2017;
80	Yamakawa et al., 2018). Dot plots were generated using EZR
81	(http://www.jichi.ac.jp/saitama-sct/SaitamaHP.files/statmedEN.html).
82	A total of 80 strains (42 E. coli and 38 K. pneumoniae) were used for the
83	cefotaxime hydrolysis assay, and the characteristics of these strains are presented in
84	Table 1. Of the 80 strains, 42 (22 E. coli and 20 K. pneumoniae) harbored ESBL genes
85	that were not detected in the remaining 38 strains. The most prevalent ESBL genotype
86	was the CTX-M type, and 23 strains harbored multiple ESBL genes. The results of
87	ESBL production assays using the BD Phoenix system were consistent with the
88	presence or absence of ESBL genes in all 80 strains. ESBL producers and non-
89	producers were defined as strains positive for both ESBL genes and ESBL production
90	and as strains negative for both ESBL genes and ESBL production, respectively.
91	Representative spectra of the cefotaxime hydrolysis assay analyzed using the MBT
92	STAR-BL assay are presented in Figure 1. The distribution of normalized logRQ values
93	of the strains examined is shown in Figure 2. All 42 ESBL producers were accurately

94	identified as positive. With respect to the 38 non-ESBL producers, 36 were correctly
95	identified as negative, whereas 1 strain was indeterminate and 1 strain was identified as
96	positive. The sensitivity and specificity of the cefotaxime hydrolysis assay for the
97	detection of ESBL activity were 100.0% (95% CI, 91.6–100.0) and 94.7% (95% CI,
98	82.3–99.4), respectively.
99	Our results indicate that the MBT STAR-BL assay exhibits excellent performance,
100	with high sensitivity and specificity. The results of previous studies using similar
101	detection systems were consistent with our present results, suggesting that the assay is
102	reliable for the detection of ESBL-producing strains (Oviano et al., 2014; Oviano et al.,
103	2017). The resistance of the two non-ESBL producers identified as indeterminate or
104	positive by the cefotaxime hydrolysis assay could be associated with plasmid-mediated
105	inducible $\beta$ -lactamases not evaluated in this study (Empel et al., 2010; Jacoby, 2009;
106	Yong et al., 2005).
107	There are some limitations to the present study. First, we examined only cefotaxime
108	under a single condition (concentration, 0.5 mg/mL; incubation time, 2 h). However, it
109	should be recognized that differences in bacterial concentration, antibiotic, drug
110	concentration, and incubation time could affect the results of this assay (Mirande et al.,
111	2015; Monteferrante et al., 2016). In addition, we used strains isolated at a single

113differences could have affected the results, further studies using strains isolated in oth114regions and including a variety of genotypes will be necessary in order to confirm the115assay performance.116In conclusion, this study demonstrated that the MBT STAR-BL assay enables117detection of ESBL-producing <i>Enterobacteriaceae</i> with high accuracy, thereby makin,118suitable for screening ESBL producers.119Reagents, instrumentation, and funding were provided by Bruker Daltonics K.K.120This study was partially supported by Health and Labour Sciences Research Grants121from the Ministry of Health, Labour and Welfare, Japan (H28-Shinkou-Ippan-003) at122a grant for research and development of diagnostic methods and therapies for123antimicrobial-resistant bacteria from the Japan Agency for Medical Research and124Development (AMED) (JP18fk0108052).125This work was presented at the 28 <sup>th</sup> European Congress of Clinical Microbiology in126Infectious Diseases (ECCMID) and at the 17 <sup>th</sup> Asia-Pacific Congress of Clinical Microbiology in	112	institution, and CTX-M was the major genotype of these strains.
