19 Running title: Species-specific pathogenicity of SFTSV

20

21 **ABSTRACT**

22        Severe fever with thrombocytopenia syndrome virus (SFTSV) is a novel  
23 emerging virus that has been identified in China, South Korea, and Japan, and induces  
24 thrombocytopenia and leukocytopenia in humans with a high case fatality rate. SFTSV  
25 is pathogenic to humans, while immunocompetent adult mice and golden Syrian  
26 hamsters infected with SFTSV never show apparent symptoms. However, mice  
27 deficient for the gene encoding the  $\alpha$  chain of the interferon (IFN)  $\alpha$  and  $\beta$  receptor  
28 (*Ifnar1*<sup>-/-</sup> mice) and golden Syrian hamsters deficient for the gene encoding signal  
29 transducer and activator of transcription 2 (*Stat2*<sup>-/-</sup> hamsters) are highly susceptible to  
30 SFTSV infection, with infection resulting in death. The nonstructural protein (NSs) of  
31 SFTSV has been reported to inhibit the type I IFN response through sequestration of  
32 human STAT proteins. Here, we demonstrated that SFTSV induces lethal acute disease  
33 in STAT2-deficient mice, but not in STAT1-deficient mice. Furthermore, we discovered  
34 that NSs cannot inhibit type I IFN signaling in murine cells due to an inability to bind to  
35 murine STAT2. Taken together, our results imply that the dysfunction of NSs in  
36 antagonizing murine STAT2 can lead to inefficient replication and the loss of  
37 pathogenesis of SFTSV in mice.

38

39 **IMPORTANCE**

40           Severe fever with thrombocytopenia syndrome (SFTS) is an emerging infectious  
41 disease caused by SFTS virus (SFTSV), which has been reported in China, South Korea,  
42 and Japan. Here, we revealed that mice lacking STAT2, which is an important factor for  
43 antiviral innate immunity, are highly susceptible to SFTSV infection. We also show that  
44 SFTSV NSs cannot exert its anti-innate immunity activity in mice due to the inability of  
45 the protein to bind to murine STAT2. Our findings suggest that the dysfunction of  
46 SFTSV NSs as an IFN antagonist in murine cells confers a loss of pathogenicity of  
47 SFTSV in mice.

50

51 **INTRODUCTION**

52           Severe fever with thrombocytopenia syndrome (SFTS) is an emerging infectious  
53 disease caused by the SFTS virus (SFTSV), which is a novel *Phlebovirus* of the  
54 *Phenuiviridae* family. SFTSV was first isolated in rural areas of central China in 2011  
55 and subsequently identified in South Korea and Japan (1-4). Moreover, another  
56 emerging phlebovirus genetically close to SFTSV, Hartland virus, was found in the  
57 United States (5). SFTS is clinically characterized by fever, vomiting, diarrhea,  
58 thrombocytopenia, leukocytopenia, and elevated serum levels of enzymes, such as  
59 creatine kinase (CK), aspartate aminotransferase (AST), alanine transaminase (ALT),  
60 and lactate dehydrogenase (LDH) (6-8). However, the pathogenesis of SFTSV in  
61 humans is still poorly understood, and no effective vaccines or antiviral drugs are  
62 currently available for treatment of SFTS.

63           The SFTSV genome is composed of three negative-strand RNA segments (S, M,  
64 and L). The L segment encodes the viral RNA-dependent RNA polymerase (L), the M  
65 segment encodes the glycoprotein precursors (Gn and Gc), and the S segment encodes  
66 the nucleocapsid protein (N) and nonstructural protein (NSs).

67           The innate immune response, including the type I interferon (IFN) response, is  
68 important for preventing viral infection (9). Antiviral innate immunity is initiated by the

69 recognition of viral infection through cellular pattern recognition receptors (PRRs), such  
70 as transmembrane toll-like receptor 3 (TLR3), cytosolic RIG-I-like receptors, and  
71 MDA5 (10). Upon recognition, this signal cascade leads to the induction of type I IFN.  
72 The activation of the IFN signaling pathway by the binding of secreted IFN to IFN  
73 receptors results in the phosphorylation of STAT1 and STAT2. The heterodimer or  
74 homodimer of phosphorylated STAT forms heterotrimeric interferon-stimulated gene  
75 factor 3 (ISGF3) with IRF-9. The translocation of ISGF3 into the cell nucleus results in  
76 the activation of antiviral IFN-stimulated genes (ISGs) by its binding to an  
77 IFN-stimulated response element (ISRE) (11). However, during a phlebovirus infection,  
78 viral NSs is thought to play a major role in repressing the innate immune response by  
79 targeting the IFN response pathway as an IFN antagonist (12-15). Previous studies have  
80 reported that NSs of SFTSV inhibits type I and III IFN responses through sequestration  
81 of human STAT2 protein in viral replication complexes (13-15).

82 SFTSV infections do not cause severe disease in immunocompetent mice and  
83 golden Syrian hamsters, while type I IFN receptor knock-out (*Ifnar1*<sup>-/-</sup>) mice, which  
84 lack the gene encoding the  $\alpha$  chain of the IFN  $\alpha$  and  $\beta$  receptor, and STAT2-deficient  
85 golden Syrian hamsters are highly susceptible to SFTSV, with infection resulting in  
86 death (16-19). This suggests that efficient replication of SFTSV in mice and hamsters is

87 prevented by antiviral innate immunity and that NSs of SFTSV does not inhibit IFN  
88 signaling in murine and hamster cells. STAT1 and STAT2 are important factors for  
89 antiviral innate immunity. However, the relationship between SFTSV pathogenicity and  
90 STAT function remains unknown. In this study, to investigate the role of STAT1 and  
91 STAT2 in the pathogenesis and replication of SFTSV in mice, we examined the  
92 pathogenicity of SFTSV in *Stat1*<sup>-/-</sup> and *Stat2*<sup>-/-</sup> mice and measured the antagonistic  
93 activities of NSs against IFN signaling in murine cells.  
94

95 **RESULTS**

96 **SFTSV infection to *Ifnar1*<sup>-/-</sup> mice.**

97         It has been reported that *Ifnar1*<sup>-/-</sup> mice are highly susceptible to SFTSV strains  
98 YL-1 and SPL010, with infection resulting in death (16-17). In this study, we used the  
99 YG-1 strain isolated from the first SFTS patient reported in Japan (4). Wild-type  
100 C57BL/6 mice and *Ifnar1*<sup>-/-</sup> mice were intradermally (id) inoculated with 10 focus  
101 forming units (FFU) of the SFTSV (YG-1). All infected wild-type mice survived  
102 without any clinical signs (Fig. 1A). In contrast, all infected *Ifnar1*<sup>-/-</sup> mice died 5 to 8  
103 days after infection (Fig. 1A). Moreover, all *Ifnar1*<sup>-/-</sup> mice infected with SFTSV showed  
104 severe body weight loss, leukocytopenia, and thrombocytopenia 1–7 days postinfection  
105 (pi) (Fig. 1B–D). The titers of SFTSV in the organs (brains, lungs, livers, spleens,  
106 kidneys, and intestines) and plasma of infected *Ifnar1*<sup>-/-</sup> and wild-type mice were also  
107 measured by focus forming assay at 3, 5, and 7 days pi. As shown in Fig. 2, efficient  
108 viral replication in *Ifnar1*<sup>-/-</sup> mice was observed in the spleen and plasma at 3 days pi, all  
109 organs at 5 days pi, and the spleen, kidney, and intestine at 7 days pi. In contrast, we  
110 could not detect infectious SFTSV in the plasma or organs of wild-type mice.

111         The results show that the SFTSV (YG-1) induces lethal acute infection  
112 accompanied by thrombocytopenia in *Ifnar1*<sup>-/-</sup> mice.

113

114 **SFTSV causes lethal infection in *Stat2*<sup>-/-</sup> mice, but not *Stat1*<sup>-/-</sup> mice.**

115         Next, to investigate the roles of STAT1 and STAT2 in SFTSV infection, *Stat1*<sup>-/-</sup>,  
116 *Stat2*<sup>-/-</sup>, and *Ifnar1*<sup>-/-</sup> mice were infected with YG-1 strain. None of the infected *Stat2*<sup>-/-</sup>  
117 mice survived, while all of the *Stat1*<sup>-/-</sup> mice infected with YG-1 survived (Fig. 1A). As  
118 shown in Fig. 1B, *Stat2*<sup>-/-</sup> mice lost body weight at 1–7 days pi, while *Stat1*<sup>-/-</sup> mice lost  
119 body weight at 1-5 days pi, and then recovered. Unlike in *Ifnar1*<sup>-/-</sup> mice, the number of  
120 white blood cells in *Stat1*<sup>-/-</sup> and *Stat2*<sup>-/-</sup> mice transiently decreased after infection and  
121 then recovered to normal values (Fig. 1C). Both *Stat1*<sup>-/-</sup> and *Stat2*<sup>-/-</sup> mice infected with  
122 SFTSV showed thrombocytopenia regardless of survival (Fig. 1D). This implies that the  
123 lethality of SFTSV is not associated with thrombocytopenia. Next, we measured the  
124 titers of SFTSV in organs (brains, lungs, livers, spleens, kidneys, and intestines) and  
125 plasma of infected *Stat1*<sup>-/-</sup> and *Stat2*<sup>-/-</sup> mice by focus forming assay at 3, 5, and 7 days pi.  
126 In *Stat2*<sup>-/-</sup> mice, SFTSV was detected in the plasma, spleen, and kidney at 3 days pi, the  
127 plasma and all organs at 5 days pi, and the spleen and kidney at 7 days pi. In *Stat1*<sup>-/-</sup>  
128 mice, SFTSV replicated in the lung, spleen, kidney, intestine, and plasma; however, the  
129 maximum titers of SFTSV in these organs and plasma were lower than those in *Stat2*<sup>-/-</sup>  
130 mice (Fig. 2).

131           These results indicate that *Stat2*<sup>-/-</sup> and *Ifnar1*<sup>-/-</sup> mice, but not *Stat1*<sup>-/-</sup> mice, are  
132 highly susceptible to SFTSV infection, which suggests that STAT2 plays a critical role  
133 in the suppression of SFTSV replication in mice.

134

135 **SFTSV NSs cannot suppress type I IFN signaling in murine cells.**

136           It has been reported that SFTSV suppress type I IFN signaling in human cells (13).  
137 Therefore, we hypothesized that SFTSV cannot suppress type I IFN signaling in murine  
138 cells, and IFN-mediated innate immunity restricts SFTSV replication in mice. To  
139 address this possibility, the ISRE activation by SFTSV infection was examined in  
140 human-derived HEK293T cells and mouse-derived NIH3T3 cells using dual-luciferase  
141 reporter (DLR) gene assay. As shown in Fig 3A, SFTSV infection did not induce the  
142 ISRE activation in HEK293T cells, while the ISRE activation was induced by SFTSV  
143 infection in NIH3T3 cells. These results suggest that SFTSV cannot inhibit type I IFN  
144 signaling in murine cells.

145           Recently, SFTSV NSs has been reported to function as an IFN antagonist (13-15).,  
146 Therefore, the effects of NSs on ISRE activation in HEK293T cells and NIH3T3 cells  
147 were examined by DLR gene assay. In this experiment, the VP40 protein of  
148 mouse-adapted Marburg virus (mMARV), which functions as an IFN signaling inhibitor

149 in murine cells, was used as a positive control (20). As shown in Fig. 3B, IFN- $\alpha$ /D  
150 treatment induced strong ISRE activation in both HEK293T and NIH3T3 cells. As  
151 expected, the expression of SFTSV NSs significantly inhibited the ISRE activation  
152 driven by IFN- $\alpha$ /D in HEK293T cells, while NSs expression did not suppress this  
153 activation in NIH3T3 cells (Fig. 3B). We also confirmed that the ISRE activation driven  
154 by IFN- $\alpha$ /D in NIH3T3 cells was suppressed by the expression of mMARV VP40 (Fig.  
155 3C). These results suggest that SFTSV NSs cannot interfere with type I IFN signaling in  
156 murine cells.

157 We also examined the effect of NSs on IFN- $\alpha$ /D-induced expression of mRNA  
158 for two ISGs, ISG56 and oligoadenylate synthetase 1 (OAS1), by real-time qPCR. The  
159 induction of both ISGs by IFN in HEK293T cells was suppressed by NSs expression,  
160 whereas NSs did not suppress induction in NIH3T3 cells (Fig. 3D).

161

#### 162 **NSs does not interact with murine and hamster STAT2.**

163 SFTSV NSs inhibits type I IFN signaling by the interaction with human STAT1  
164 (hSTAT1) and STAT2 (hSTAT2) (13-15). However, the interaction with hSTAT1 is  
165 weaker than that with hSTAT2 (15). We also showed here that mice deficient for STAT2,  
166 but not STAT1, were highly susceptible to SFTSV infection and progressed to severe

167 disease (Fig1). Therefore, we suggest that NSs cannot interact with murine STAT2 and  
168 thus cannot antagonize IFN signaling in murine cells.

169 First, to examine whether NSs interacts with murine STAT2 (mSTAT2), we  
170 performed co-immunoprecipitation (co-IP) assays using lysates from cells transfected  
171 with a NSs expression plasmid. As shown in Fig. 4A, co-IP of STAT2 with NSs was  
172 observed only in the lysates from HEK293T cells, but not from NIH3T3 cells,  
173 suggesting that NSs interact with hSTAT2 but not with mSTAT2. It was also indicated  
174 that NSs bound to hSTAT1, but not to murine STAT1 (mSTAT1) (Fig. 4A).

175 We also examined the interaction of NSs with hamster STAT2 (hamSTAT2) by  
176 co-IP assay, since *Stat2*<sup>-/-</sup> hamsters, like *Stat2*<sup>-/-</sup> mice, are highly susceptible to SFTSV  
177 infection (19). As shown in Fig. 4B, the interaction of NSs with hamSTAT2, as well as  
178 mSTAT2, was not observed.

179 The interaction of NSs with STAT2 was also examined by subcellular  
180 colocalization of the proteins. The NSs expression plasmid was cotransfected with the  
181 expression plasmids for hSTAT2, mSTAT2, or hamSTAT2 into HEK293T, NIH3T3, or  
182 BHK-21 cells, respectively, and subcellular localizations of proteins were observed.  
183 Cytoplasmic inclusion bodies (IBs), mainly formed by NSs, were also observed in  
184 HEK293T, NIH3T3, and BHK-21 cells (Fig. 4C). In HEK293T cells, hSTAT2

185 colocalizes with NSs, consistent with previous reports (13-15). On the other hand, in  
186 NIH3T3 and BHK-21 cells, colocalization of NSs with mSTAT2 or hamSTAT2 was not  
187 observed (Fig. 4C). These findings indicate that NSs interacts with hSTAT2, but not  
188 mSTAT2 and hamSTAT2.

189

### 190 **The N-terminal region of hSTAT2 is important for binding to NSs.**

191 To investigate the difference in NSs binding between human and murine STAT2,  
192 we prepared a series of chimeric proteins from hSTAT2 and mSTAT2 (Fig. 5A). The  
193 interactions between NSs and the chimeric STAT2 proteins were examined by co-IP  
194 assay. All chimeric proteins efficiently expressed in NIH3T3 cells (Fig. 5B). As shown  
195 in Fig. 5B, NSs interacted with hSTAT2, HHM, HMM, H(101–315)MM, and H(101–  
196 315)HM, but not mSTAT2, MHH, MMH, H(1–100)MM, H(1–221)MM and H(222–  
197 315)MM.

198 We also confirmed the results by observation of colocalization of the proteins (Fig.  
199 5C). NSs colocalized with hSTAT2, HHM, HMM, H(101–315)MM and H(101–  
200 315)HM, while mSTAT2, MHH, MMH, H(1–100)MM, H(1–221)MM, and H(222–  
201 315)MM, did not colocalize with NSs. These results are consistent with those from the  
202 co-IP assay. It has been reported that SFTSV NSs interacts with the DNA-binding

203 domain (DBD: amino acid position 316–485) of hSTAT2 (13). Taken together, these  
204 results suggest that region 101–315 of hSTAT2 is important for the binding to NSs in  
205 addition to the DBD, or that this region of mSTAT2 interferes with the binding to NSs.

206 To further examine whether MHH and MMH, which cannot bind to NSs, function  
207 as STAT2 proteins in the presence of NSs, ISRE activation by MHH or MMH in the  
208 presence of NSs was investigated by the DLR assay in HEK293T cells. ISRE activation  
209 was reduced by NSs in the absence of exogenous STAT2, and overexpression of  
210 exogenous hSTAT2 slightly compensated for this reduction induced by NSs (Fig. 6). In  
211 contrast, the suppression of ISRE activation by NSs was significantly recovered by  
212 mSTAT2, MMH, and MHH, suggesting that MMH and MHH, as well as mSTAT2,  
213 activate ISRE as a functional STAT2 protein in the presence of NSs in HEK293T cells.

214

#### 215 **Type I IFN induces the phosphorylation of mSTAT2 in the presence of NSs.**

216 Tyrosine phosphorylation of STAT2 is important for its function as a transcription  
217 factor in the type I IFN signaling pathway (21). To assess whether type I IFN signaling  
218 can phosphorylate mSTAT2 in the presence of NSs, HEK293T and NIH3T3 cells were  
219 transfected with empty vector or the NSs-HA expression plasmid, and then treated with  
220 IFN- $\alpha$ A/D. The expression levels of hSTAT2 and mSTAT2 were stable regardless of

221 NSs expression (Fig. 7A). In the absence of NSs, IFN induced the phosphorylation of  
222 hSTAT2 and mSTAT2. hSTAT2 phosphorylation in HEK293T cells was significantly  
223 downregulated by NSs in a concentration-dependent manner. In contrast, mSTAT2 in  
224 NIH3T3 cells was phosphorylated irrespective of NSs expression (Fig. 7A). These were  
225 also observed in SFTSV infected cells (Fig. 7B). It is likely that NSs cannot interfere  
226 with the phosphorylation of mSTAT2, since NSs cannot bind to mSTAT2.  
227

228 **DISCUSSION**

229 Previous studies in animal models of SFTSV infection indicated the importance  
230 of the type I IFN response in mice and STAT2 in hamsters to prevent disease  
231 progression (16-17, 19). Both STAT1 and STAT2 have been found to be key factors in  
232 the IFN signaling pathway (21). In this study, we demonstrated that STAT2-deficient  
233 mice, as well as type I IFN receptor-deficient mice, are more susceptible to SFTSV than  
234 STAT1-deficient mice and wild-type mice. Moreover, our results indicate that NSs has  
235 no ability to suppress the IFN signaling pathway in murine cells because NSs, which  
236 binds hSTAT1 and hSTAT2, cannot interact with mSTAT1 and mSTAT2. The SFTSV  
237 growth in the organs of *Stat1*<sup>-/-</sup> mice were much less efficient than those in *Stat2*<sup>-/-</sup> and  
238 *Ifnar1*<sup>-/-</sup> mice, although SFTSV could grow in *Stat1*<sup>-/-</sup> mice (Fig. 2). In addition, SFTSV  
239 infection induced milder symptom in *Stat1*<sup>-/-</sup> mice than in *Stat2*<sup>-/-</sup> and *Ifnar1*<sup>-/-</sup> mice (Fig.  
240 1). These suggests that innate immunity dependent on STAT2, but not STAT1, strongly  
241 inhibits the replication of SFTSV in mice. In several human cell lines, the expression of  
242 some ISGs is upregulated by STAT2, independent of STAT1 (22). For example, the  
243 expression levels of several ISGs including APOBEC3G, PKR, ISG15, and Mx1 are  
244 increased by type I IFN stimulation regardless of STAT1 expression in the human liver  
245 cell lines, Huh7 and Hep3B. However, when the expression of STAT2 is suppressed, the

246 expression levels of these ISGs are not increased after type I IFN treatment. These  
247 findings suggest that ISGs expression mediated by STAT2, but not STAT1, suppress  
248 mainly SFTSV infection in mice.

249 SFTSV causes severe disease in human, while immunocompetent adult mice  
250 never show any apparent severe symptoms after SFTSV infection (18). In this study, we  
251 showed that mice lacking STAT2 are highly susceptible to SFTSV infection. Moreover,  
252 NSs can suppress the phosphorylation of hSTAT2, whereas the phosphorylation of  
253 mSTAT2 is not inhibited by NSs due to the inability of NSs to bind to mSTAT2. The  
254 data also indicates that NSs cannot interact with hamSTAT2. This result is consistent  
255 with a previous report showed that STAT2-deficient hamsters are also highly susceptible  
256 to SFTSV infection (19).

257 The relationship between NSs and STAT2 is reminiscent of that of dengue virus  
258 NS5 and STAT2 (A23-25). Previous studies reported that innate immunity mediated by  
259 mSTAT2 restricts dengue virus replication in mice (25-26). To block the type I IFN  
260 signaling pathway in humans, dengue virus NS5 expression leads to the degradation of  
261 hSTAT2 (25). However, NS5 cannot suppress type I IFN signaling in mice, because  
262 mSTAT2 is resistance to NS5-mediated degradation (23-25). These results demonstrate  
263 that STAT2 may be one of the determinants for the species specificity of dengue virus.

264 Here, we elucidated that SFTSV induces lethal disease in STAT2-deficient mice and that  
265 NSs cannot interact with mSTAT2. Thus, similar to dengue virus NS5, the anti-STAT2  
266 activity of NSs appears to determine the species specificity of SFTSV infection.

267 In this study, chimeric mutants of hSTAT2 and mSTAT2 revealed that residues  
268 101–315 of hSTAT2 are required for the interaction with NSs or that these residues in  
269 mSTAT2 interfere with the interaction with NSs. We also confirmed that mSTAT2 and  
270 all of the chimeric mutants of hSTAT2 and mSTAT2 used in this study can activate  
271 ISRE-mediated gene expression as functional STAT2 proteins. Previously, Ning *et al.*  
272 reported that the DBD region (316–485) of hSTAT2 is required for the interaction with  
273 NSs (13). However, we showed that mutants possessing the DBD region of mSTAT2,  
274 HMM, and H(101–315)MM, can still bind to NSs (Fig. 5). At present, we cannot  
275 explain this result, although this discrepancy may be explained by the differences in the  
276 three-dimensional protein structure between our mutants and Ning's deletion mutants.  
277 Further analyses will be required to clarify this issue.

278 Taken together, we conclude that the anti-STAT2 activity of NSs determines the  
279 species specificity of SFTSV infection. In addition, we show that *Stat2*<sup>-/-</sup> mice, as well  
280 as *Ifnar1*<sup>-/-</sup> mice and *Stat2*<sup>-/-</sup> hamsters, are highly susceptible to SFTSV infection, which  
281 causes lethal disease, suggesting that *Stat2*<sup>-/-</sup> mice may be useful as an animal model to

282 develop antiviral drugs against SFTSV infection.

283

284 **MATERIALS AND METHODS**

285 **Ethics statement.**

286 Our research protocol for the use of mice follows the Nagasaki University Regulations  
287 for Animal Care and Use, which was approved by the Animal Experiment Committee of  
288 Nagasaki University (approval number; 151110-1-5).

289

290 **Animals.**

291 B6.129-Dnase2a<sup>tm10sa</sup>Ifnar1<sup>tm1Agt</sup> mouse strain (RBRC04021; *Ifnar1*<sup>-/-</sup>  
292 *Dnase2a*<sup>+/-</sup>) (27) was provided by RIKEN BRC through the National BioResource  
293 Project of MEXT, Japan. *Ifnar1*<sup>-/-</sup> mice were generated by crossing *Dnase2a*<sup>+/-</sup> *Ifnar1*<sup>-/-</sup>  
294 parents. *Stat1*<sup>-/-</sup> mice were provided by Dr. Takayuki Yoshimoto (Tokyo Medical  
295 University). *Stat2*<sup>-/-</sup> mice were purchased from the Jackson Laboratory. The genetical  
296 backgrounds of all mice used in this study are C57BL/6.

297

298 **SFTSV infection in mice.**

299 Six- to eight-week-old male or female mice were used in this study. In infection  
300 experiments, each mouse was infected with SFTSV by intradermal injection (50 µL of  
301 virus solution for 10 FFU). Mouse survival and body weight changes were monitored

302 daily for 14 days pi. At 1, 3, and 7 days pi, blood was collected, and platelets and  
303 leukocytes were counted using a hematology analyzer (Sysmex pocH-100iV; Sysmex or  
304 VetScan HMII; Abaxis). Mice were euthanized, and plasma and organs (lungs, livers,  
305 spleens, kidneys, intestines, and brains) were collected. Viruses in plasma were titrated  
306 by focus forming assay using Vero E6 cells. To determine the titer of SFTSV in organs,  
307 mouse organs were collected in a 9-fold volume of minimum essential media  
308 (Sigma-Aldrich) and then disrupted through high-speed shaking using TissueLyser II  
309 (Qiagen). After centrifugation (700 x g, 5min, 4°C), the amounts of viruses in the  
310 homogenates (10% w/v) were determined by focus forming assay in VeroE6 cells. The  
311 limit of detection is 100FFU/g.

312

### 313 **Cell culture and virus.**

314 Human embryonic kidney (HEK) 293T (CRL-11268; ATCC), NIH3T3 (CRL-1658;  
315 ATCC), BHK-21 (JCRB9020; Health Science Research Resources Bank (HSRRB)),  
316 and Vero E6 (CRL-1586; ATCC) cells were cultured in Dulbecco modified Eagle  
317 medium (Sigma-Aldrich) supplemented with 10% heat-inactivated (fetal calf serum)  
318 FCS and antibiotics (Thermo Fisher Scientific). The SFTSV (YG1), a field isolate from  
319 an SFTS patient in Japan, was kindly provided by Dr. Ken Maeda, Yamaguchi

320 University (28). The virus stocks were prepared from culture supernatants of Vero E6  
321 cells.

322

323 **Focus forming assay.**

324 SFTSV titers were determined using a focus forming assay. Briefly, confluent  
325 monolayers of Vero E6 cells were inoculated with 10-fold dilutions of SFTSV and  
326 incubated at 37°C for 1 hour. The inoculum was removed, and cells were washed and  
327 overlaid with MEM (Sigma-Aldrich) containing 0.7% agarose and 0.7% FCS. After 4  
328 days, cells were fixed with 4% paraformaldehyde and permeabilized with  
329 phosphate-buffered saline (PBS) containing 1% Triton X-100. Cells were blocked with  
330 PBS containing 0.1% Triton X-100 and 1% bovine serum albumin (BSA), and then  
331 incubated with anti-SFTSV N protein rabbit polyclonal antibody (28). After washing  
332 with PBS, the cells were incubated with anti-rabbit IgG conjugated with horseradish  
333 peroxidase (Promega). After more washes with PBS, SFTSV-infected cells were  
334 detected by using Peroxidase Stain DAB Kit and Metal Enhancer for DAB Stain  
335 (Nacalai Tesque). The number of SFTSV N positive cells were determined and  
336 normalized as FFU/ml.

337

338 **Plasmids.**

339 The open reading frame (ORF) encoding NSs was amplified by reverse transcription  
340 PCR (RT-PCR) from SFTSV (YG-1) viral RNA and inserted into pcDNA3.1  
341 (Invitrogen) with a hemagglutinin (HA) tag using the primers listed in Table 1 to  
342 produce pcDNA3.1/NSs-HA. To prepare the expression plasmids for 6xHistidine  
343 (His)-tagged hSTAT2 (pcDNA3.1/hSTAT2-His), mSTAT2 (pcDNA3.1/mSTAT2-His),  
344 and hamSTAT2 (pcDNA3.1/hamSTAT2-His), the desired genes were amplified by  
345 RT-PCR using the primers listed in Table 1 from the cDNA of HEK293T, NIH3T3, and  
346 BHK-21 cells, respectively. The expression plasmids for the series of STAT2 chimeras  
347 were constructed using an In-Fusion HD Cloning kit (TaKaRa) with the primers listed  
348 in Table 1. The expression plasmid for mMARV VP40 was constructed from MARV  
349 VP40 (28) using a KOD-Plus-Mutagenesis Kit (TOYOBO) using the primers listed in  
350 Table 1.

351

352 **Reporter gene assay.**

353 HEK293T cells and NIH3T3 cells were cotransfected with ISRE reporter plasmid (450  
354 ng) (Promega) and pRL-TK plasmid [the *Renilla* luciferase control plasmid for the  
355 constitutively active herpes simplex virus (HSV)-thymidine kinase (TK) promoter] (100

356 ng) (Promega). Twenty-four hours after transfection, the transfected cells were  
357 mock-infected or infected with SFTSV. Two days after infection, luciferase activities  
358 were measured with a DLR assay kit (Promega) and a TriStar LB941 system (Berthold).  
359 For the reporter gene assays with SFTSV NSs transfection, the ISRE reporter plasmid  
360 (500 ng) (Promega) and pRL-TK [the *Renilla* luciferase control plasmid for the  
361 constitutively active herpes simplex virus (HSV)-thymidine kinase (TK) promoter]  
362 plasmid (100 ng) (Promega) were transfected into HEK293T and NIH3T3 cells with or  
363 without the indicated amount of pcDNA3.1/NSs-HA plasmid or the expression plasmid  
364 for mMARV VP40 (800 ng) using LT-1 (Mirus) or Lipofectamine 3000 (Thermo Fisher  
365 Scientific) according to the manufacturer's instructions. Twenty-four hours after  
366 transfection, cells were treated with IFN- $\alpha$ A/D (500 U/ml) (Sigma-Aldrich) or were left  
367 untreated for 18 h. Luciferase activities then were measured with a DLR assay kit  
368 (Promega) and a TriStar LB941 system (Berthold).

369

#### 370 **Quantitative real-time reverse transcription PCR (RT-PCR) of IFN-treated cells.**

371 Total RNA was extracted from HEK293T and NIH3T3 cells using an RNeasy Mini kit  
372 (Qiagen). Real-time RT-PCR was performed by using the One Step TB Green™  
373 PrimeScript™ PLUS RT-PCR Kit (TaKaRa) according to the manufacturer's

374 instructions, and the PCR primers used in this study are listed in Table 1. Relative  
375 mRNA levels were calculated by the  $2^{-\Delta\Delta CT}$  method with *GAPDH* mRNA as an internal  
376 control and are shown as relative fold changes normalized to the untreated control  
377 samples.

378

### 379 **Immunoblotting.**

380 Protein samples were separated by SDS-PAGE and transferred to nitrocellulose  
381 membranes (Millipore). After blocking with 5% skim milk in Tris-buffered  
382 saline/Tween 20 (TBS-T), the membranes were incubated with each of the following  
383 antibodies: anti-HA (18850; QED Biosciences Inc.), anti-His (9F2; Wako), anti-hSTAT2  
384 (A-9; Santa Cruz), anti-mSTAT2 (07-140; Merc), anti-STAT2 (phosphor Y690)  
385 (ab53132; Abcam), anti-STAT1 (D19KY; Cell signaling) or anti- $\beta$  actin (AC-15;  
386 Sigma-Aldrich). After washing with TBS-T, the membranes were incubated with  
387 horseradish peroxidase-labeled secondary antibodies, Anti-Mouse IgG-HRP (A2304;  
388 Sigma-Aldrich) or Anti-Rabbit IgG-HRP (WA4011; Promega), and then detected using  
389 ECL prime (GE Healthcare) according to the manufacturer's instructions. Bands were  
390 visualized using an image analyzer (LAS-4000 mini; GE Healthcare).

391

392 **Co-IP assay.**

393 To examine the binding of NSs to endogenous STAT2, the pcDNA3.1/NSs-HA plasmid  
394 (15 µg) was transfected into HEK293T and NIH3T3 cells in 10-cm dishes (Thermo  
395 Fisher Scientific) using LT-1 or Lipofectamine 3000, respectively. To examine the  
396 binding of NSs to exogenous STAT2 or STAT2 derivatives, the pcDNA3.1/NSs-HA  
397 plasmid (3 µg) was cotransfected into NIH3T3 cells with each STAT2 expression  
398 plasmid (1 µg) in 6-well plates (Thermo Fisher Scientific) using Lipofectamine 3000.  
399 Two days after transfection, cells were lysed in lysis buffer (25 mM Tris-HCl, 150 mM  
400 NaCl, 1 mM EDTA, and 1% Triton X-100) containing a protease inhibitor cocktail  
401 (Roche). To perform the co-IP assay, cell lysates were mixed with magnetic beads  
402 conjugated to an anti-His monoclonal antibody (OGHis; MBL) or anti-HA monoclonal  
403 antibody (5D8; MBL) and incubated at 4°C for 3 h or overnight, respectively. Then, the  
404 magnetic beads were washed with lysis buffer and wash buffer (50 mM Tris-HCl, 1%  
405 NP-40, 0.25% deoxycholic acid sodium salt, 150 mM NaCl, and 1 mM EDTA) and  
406 analyzed by immunoblotting as described above.

407

408 **Immunofluorescence assay (IFA).**

409 The expression plasmids for His-tagged hSTAT2, mSTAT2, hamSTAT2, or a series of

410 STAT2 chimeras were cotransfected into HEK293T, NIH3T3, or BHK-21 cells with the  
411 pcDNA3.1/NSs-HA plasmid. Twenty-four hours after transfection, transfected cells  
412 were fixed using 4% paraformaldehyde-PBS (Wako), and then the fixed cells were  
413 incubated in 1% Triton X-100 in PBS for permeabilization and blocked in 10% FCS in  
414 blocking buffer (3% BSA and 0.3% Triton X-100 in PBS). Cells then were treated with  
415 primary antibodies (anti-HA (18850; QED Biosciences Inc.) or anti-His (9F2; Wako))  
416 overnight at 4°C and stained with secondary antibodies (Anti-Rabbit IgG - H&L (FITC)  
417 (ab6009; abcam) or Anti-Mouse IgG (whole molecule) –TRITC (T5393;  
418 Sigma-Aldrich)) for 2 h at room temperature with DAPI (Roche) for visualization of  
419 nuclei. Image acquisition was performed with a LSM780 microscope (Carl Zeiss)

420

421 **Statistical analyses.** Significant differences in virus titers in mouse organs among  
422 mouse strains were determined by one-way ANOVA following Tukey's multiple  
423 comparisons test using GraphPad Prism software. And statistically significant  
424 differences in the data of Fig3A, 3B, 3C, 3D and 6 were determined using Student's  
425 *t*-test (Fig3A, 3C and 3D) or Dunnett's test (Fig 3B and 6).

426

427 **ACKNOWLEDGMENTS**

428 We would like to thank Dr. K. Maeda (Yamaguchi University, Yamaguchi, Japan) and  
429 Dr. T. Yoshimoto (Tokyo Medical University, Tokyo, Japan) for providing the SFTSV  
430 YG1 strain and *Stat1*<sup>-/-</sup> mice, respectively. We also would like to thank Dr. S. Morikawa  
431 and Dr. S. Fukushi (National Institute of Infectious Diseases, Tokyo, Japan) for  
432 providing the anti-SFTSV N antibody. We are grateful to all the members of the  
433 Department of Emerging Infectious Diseases, Institute of Tropical Medicine, Nagasaki  
434 University. This research was supported by a grant from the Japan Agency for Medical  
435 Research and Development (AMED) under Grant Number JP18fk0108202h0805 (JY),  
436 the Japan Society for the Promotion of Science under Grant Number 15J06242 (RY),  
437 and the Takeda Science Foundation (RY).

555 **FIGURE LEGENDS**

556 Fig. 1. Clinical pathologies of mice infected with SFTSV. Wild-type C57BL/6 (WT),  
557 *Ifnar1<sup>-/-</sup>*, *Stat1<sup>-/-</sup>*, and *Stat2<sup>-/-</sup>* mice were infected with 10 FFU of SFTSV (YG1). (A)  
558 Survival and (B) body weight changes were observed daily for 14 days pi (n = 10). For  
559 WBC and PLT counts, blood samples were collected from two male and three female  
560 mice at 0, 1, 3, 5, and 7 days pi. The values are shown as mean  $\pm$  Standard Divisions  
561 (SDs).

562

563 Fig. 2. Titers of SFTSV in mouse organs. Mice were inoculated with 10 FFU of SFTSV  
564 YG1. Three female mice were euthanized for virus titration at 3, 5, and 7 days pi. The  
565 virus titers in the mouse brains, lungs, livers, spleens, kidneys, intestines, and plasma  
566 were measured by focus forming assay. The values are shown as mean  $\pm$  SDs (n = 3).  
567 \* $P < 0.05$ , compared among each mouse strain.

568

569 Fig. 3. The function of NSs as an IFN antagonist in human and murine cells. (A) HEK  
570 293T or NIH3T3 cells transfected with the reporter plasmids were mock-infected or  
571 infected with SFTSV. Two days after infection, cells were lysed to measure luciferase  
572 activity and to examine the protein expression using immunoblotting. Relative light  
573 units (RLU) in mock-infected cells were set as 1. Fold activation by SFTSV infection

574 are indicated. (B) The reporter plasmids were transfected into HEK293T or NIH3T3  
575 cells with or without the expression plasmid for NSs. Twenty-four hours after  
576 transfection, cells were treated with or without IFN- $\alpha$ /D (500 U/ml) for 18 hours and  
577 then were lysed to measure luciferase activity and detect protein expression using  
578 immunoblotting. RLU in cells transfected with the empty vector or the indicated amount  
579 of NSs expression plasmid in the absence of IFN- $\alpha$ /D were set as 1. Fold activation by  
580 IFN- $\alpha$ /D are indicated. (C) The experiment done in (B) was repeated using the  
581 expression plasmid for mMARV VP40 in NIH3T3 cells. (D) NSs expression plasmid (1  
582  $\mu$ g or 1.5  $\mu$ g) or control plasmid was transfected into HEK293T or NIH3T3 cells,  
583 respectively. Twenty-four hours after transfection, the cells were treated with IFN- $\alpha$ /D  
584 (200 U/ml) or left untreated for 10 hours. Expression levels of *Isg56* and *Oas1* mRNAs  
585 in each cell line were measured by real-time qPCR. The mRNA expression levels of  
586 ISG56 and OAS1 in IFN- $\alpha$ /D untreated cells were set as 1. Fold activations by  
587 IFN- $\alpha$ /D are indicated. These assays were independently performed in triplicate. The  
588 data represent averages with SDs. \*\*in panel A and B,  $P < 0.05$  versus no NSs.

589

590 Fig. 4. Interaction of NSs with STAT1 and STAT2. (A) HEK293T or NIH3T3 cells were  
591 transfected with the expression plasmid for HA-tagged NSs and co-IP assays were

592 performed. (B) NIH3T3 cells were transfected with the expression plasmids for  
593 HA-tagged NSs and His-tagged hSTAT2 or hamSTAT2. The protein expression levels in  
594 cell lysates (left) and in co-IP assays (right) using an anti-HA or anti-His antibody. (C)  
595 Colocalization of NSs with STAT2. HEK293T, NIH3T3, or BHK-21 cells were  
596 transfected with the expression plasmid for HA-tagged NSs and the expression plasmid  
597 for His-tagged hSTAT2, mSTAT2, or hamSTAT2, respectively. IFA was also performed  
598 with NSs, STAT2, and the nuclei shown in green, red, and blue, respectively.

599

600 Fig. 5. Determination of the region of hSTAT2 important for the binding to NSs. (A)  
601 Schematic representation of the chimeric mutants of hSTAT2 and mSTAT2. (B)  
602 NIH3T3 cells were cotransfected with the expression plasmids for HA-tagged NSs and  
603 each of the STAT2 His-tagged chimeras. Representative results from the protein  
604 expression check in cell lysates (upper) and the co-IP assays using an anti-His antibody  
605 (lower) are shown. (C) IFA was also performed with NSs, STAT2, and the nuclei shown  
606 in green, red, and blue, respectively.

607

608 Fig. 6. Function of the NSs binding-deficient STAT2 chimera. The reporter plasmids  
609 were cotransfected into HEK293T cells with the expression plasmids for NSs and each

610 STAT2 chimera. Twenty-four hours after transfection, cells were treated with or without  
611 IFN- $\alpha$ A/D (500 U/ml) for 18 hours and then were lysed to measure luciferase activity  
612 (upper figure) or detect protein expression using immunoblotting (lower figure). The  
613 ISRE activity was calculated by dividing RLU in IFN- $\alpha$ A/D-treated cells by the units  
614 IFN- $\alpha$ A/D untreated cells. The ISRE activity in the absence of NSs was set as 100%.  
615 The assays were independently performed in triplicate. The data represent averages with  
616 SDs. \*\*  $P < 0.05$  versus hSTAT2.

617

618 Fig. 7. Suppression of STAT2 phosphorylation by NSs. (A) HEK293T or NIH3T3 cells  
619 transfected with the expression plasmid for HA-tagged NSs were treated with  
620 IFN- $\alpha$ A/D (2000 U/ml) or left untreated for 45 minutes and were then lysed for  
621 detection of each protein expression by immunoblotting. (B) HEK293T or NIH3T3 cells  
622 infected with SFTSV at an MOI of 10 were treated with IFN- $\alpha$ A/D (2000 U/ml) or left  
623 untreated for 45 minutes and were then lysed for detection of each protein expression by  
624 immunoblotting.

625

Table 1. List of the primers used in this study

Primer name	Primer sequence	Remarks
pcDNA-NSsHA-RV-F	atccaccatgctgctgagcaaatgctccaac	For the construction of pcDNA3.1/NSs-HA
pcDNA-NSsHA-Kpn-R	gcttggtagctcaagcgaatctggaacatcgat ggatagacctccttcgggaggcacc	
humanSTAT2hisF	atccaccatggcgcagtgaggaaatgctg	For the construction of pcDNA3.1/hSTAT2-His
humanSTAT2hisR	gcttggtagctcaatggtaggtgatgatgaccg gtatgcatattgaagtcagaaggcatcaagggtcc	
mouseSTAT2hisF	atccaccatggcgcagtgaggagatgttg	For the construction of pcDNA3.1/mSTAT2-His
mouseSTAT2hisR	gcttggtagctcaatggtaggtgatgatgaccg gtatgcatattgaaggatcaagatccatcccaa	
hamSTAT2F	atccaccatggcgcagtgaggagacactg	For the construction of pcDNA3.1/hamSTAT2-His
hamSTAT2hisR	gcttggtagctcaatggtaggtgatgatgaccg gtatgcatattgtcatcagaaggaatcaagggtcc	
mSTAT2-hDBD-veF	gttcttctccaagctccgaaag	For the construction of pHHM(#1)
HMM-HHM-inR	accggtatgcatattgaaggtatc	
hmSTAT2DBDveF	aatatgcataccggatcatcatcac	
mSTAT2-hDBD-inR	gcttggcagaagaactgctggttctgaagg	
hSTAT2-mDBD-inF	acagagcctttgtagtagaaaccagccctg	For the construction of pHMM(#2)
HMM-HHM-inR	accggtatgcatattgaaggtatc	
hmSTAT2DBDveF	aatatgcataccggatcatcatcac	
hSTAT2-mDBD-veR	ctacaaaggctctgtggagcag	
mSTAT2-hDBD-inF	aaaggtcctttggttagaaaccagccc	For the construction of pMHH(#3)
MMH-MHH-inR	accggtatgcatattgaagtcag	
hmSTAT2DBDveF	aatatgcataccggatcatcatcac	
mSTAT2-hDBD-veR	ccacaaaggaccttggagcagac	
hSTAT2-mDBD-veF	gttcttctccaaccccccaag	For the construction of pMMH(#4)
MMH-MHH-inR	accggtatgcatattgaagtcag	
hmSTAT2DBDveF	aatatgcataccggatcatcatcac	
hSTAT2-mDBD-inR	gggttggagaagaactgctggttctggg	
H(1-100)MMinF	cccaggatcctaccagttggctgagatg	For the construction of pH(1-100)MM(#5)
HMM-HHM-inR	accggtatgcatattgaaggtatc	
hmSTAT2DBDveF	aatatgcataccggatcatcatcac	
H(1-100)MMVeR	gggtaggatcctgggaaaagggtgaatg	
H(1-221)MMinF	cactgctaggccgattaaccaccctgg	For the construction of pH(1-221)MM(#6)
HMM-HHM-inR	accggtatgcatattgaaggtatc	
hmSTAT2DBDveF	aatatgcataccggatcatcatcac	
H(1-221)MMVeR	atcggcctagcagtgcttggaggcatc
