Abstract. Esophageal achalasia is considered as a risk factor of esophageal cancer. The etiologies of esophageal achalasia remain unknown. Peroral endoscopic myotomy (POEM) has recently been established as a minimally invasive method with high curability. The aims of the present study were to identify the microRNAs (miRs) specific to esophageal achalasia, to determine their potential target genes and to assess their alteration following POEM. RNA was extracted from biopsy samples from middle esophageal mucosa and analyzed using a microarray. Differentially expressed miRs in achalasia patients compared with control samples were identified and analyzed using reverse transcription-quantitative polymerase chain reaction (RT-qPCR). Correlations between specific miR expression levels and the patients' clinical background were also investigated. In addition, alterations of selected miR expression levels before and after POEM were analyzed. The results of RT-qPCR analysis demonstrated that the miR-130a expression levels were significantly higher in patients with achalasia ($P < 0.0001$). In addition, miR-130a expression was significantly correlated with male sex and smoking history in patients with achalasia. However, no significant change in

miR-130a expression was observed between before and after POEM. In conclusion, miR-130a is highly expressed in the esophageal mucosa of patients with achalasia and may be a biomarker of esophageal achalasia.

Introduction

Esophageal achalasia is motility disorder resulting from incomplete relaxation of the lower esophageal sphincter (LES) and the loss of normal peristalsis (1-3). The predominant symptoms of esophageal achalasia are dysphagia and regurgitation. Patients with achalasia are diagnosed by self-reported symptoms, endoscopy and esophagography. Achalasia is a rare and chronic disease that can occur at any age (2), and is considered as a risk factor of esophageal cancer (1,3). The risk of developing squamous cell carcinoma in achalasia patients was demonstrated to be increased by 33-fold compared with that in the general population (4). However, the etiology of esophageal achalasia, particularly the process leading to carcinogenesis, remains largely unknown.

Persistent esophageal distension with retention of food and fluids, bacterial overgrowth, and impaired clearance of regurgitated acid and gastric contents are known to lead to chronic inflammation and to passively cause dysplasia and carcinoma (5-7). Therapy for esophageal achalasia aims to reduce food stagnation (8). Various treatments have been devised for achalasia patients, including medication, balloon dilatation and surgery. Endoscopic balloon dilatation remains a widely performed treatment due to the relative noninvasiveness and simplicity of the procedure; however, it has a relatively low success rate and often requires multiple treatment sessions (9). Peroral endoscopic myotomy (POEM) has been recently established as a minimally invasive procedure with high success rate (10,11). Inoue *et al* (10) reported that, in short-term results, there was no recurrence subsequent to the POEM procedure in 17 cases of achalasia. POEM can be successfully and safely performed by skilled endoscopists, and effectively ameliorates dysphagia symptoms. Manometric pressure studies have also

Key words: esophageal achalasia, etiology, microRNA, peroral endoscopic myotomy, esophageal cancer

demonstrated significant improvement in the lower esophageal sphincter pressure following POEM (11). In addition, POEM substantially decreased the Ki-67-positive and P53-positive ratios in esophageal epithelia. Thus, POEM appears to reduce the risk of esophageal carcinogenesis (11).

MicroRNAs (miRs) are small non-coding RNAs that negatively regulate gene expression via translational repression or messenger RNA degradation (12). Over 2,800 miRs have been identified in humans, with each individual miR predicted to target multiple genes based on the seed sequence matching their 3'-untranslated regions (UTRs) (13). miRs are involved in biological and pathological processes, including cell differentiation, proliferation, apoptosis and metabolism (14), and they are emerging as highly tissue-specific biomarkers with potential clinical applicability for defining cancer type and origin (15,16). Accumulating evidence has indicated that deregulation of miRs is associated with human malignancies, and suggested that miRs may have a causal role in tumor initiation and progression, since they can function as oncogenes or tumor suppressors (17). Indeed, previous studies have indicated distinct differences in miR expression patterns between squamous cell carcinoma and adenocarcinoma in esophageal and other cancer types (18-20). For instance, Kimura *et al* (21) reported that the highest expression of miR-205 was identified in both benign and malignant squamous epithelia, including in esophageal squamous cell carcinoma, whereas a lower expression was observed in cell lines and tissues other than squamous epithelia. Additionally, miR-21, which is an oncogenic miR in various malignancies, was also upregulated in esophageal squamous cell carcinoma compared with its expression in paired normal squamous epithelia (21). There is also growing evidence regarding the pathogenic roles of miRs in immune and inflammatory disorders, including esophagitis. For example, elevated miR-143, miR-145 and miR-205 expression levels were observed in the esophageal squamous mucosa of individuals with ulcerative esophagitis, where they may be involved in regulating epithelial restoration in response to injury caused by gastro-esophageal reflux (22).

As mentioned earlier, it is generally accepted that achalasia is a pre-malignant disorder that is possibly caused by longstanding mucosal inflammation due to persistent stasis of food (23). Nevertheless, there is little information regarding the miR expression profile in achalasia. Therefore, the aims of the present study were to identify the miR expression specific to the esophageal mucosa of achalasia patients, to determine potential target genes of these miRs and to assess the alteration of miRs following POEM.

Materials and methods

Patients and clinical samples. A total of 29 achalasia patients who visited the Showa University Northern Yokohama Hospital (Yokohama, Japan) between October 2011 and June 2012 were enrolled into the current study. Patients with any severe underlying illness, such as cancer, or those who could not tolerate general anesthesia were excluded. A total of 14 males and 15 females aged between 23 and 85 years (mean=46) were enrolled. There were 15 smokers and 13 non-smokers (1 unknown). They were all known to have achalasia. A total of 23 patients suffered from straight-type achalasia (the

meandering of the longitudinal axis of the esophagus appears weak on barium esophagogram) and 6 patients suffered with sigmoid-type achalasia (the meandering of the longitudinal axis of the esophagus appears strong on barium esophagogram). The degree of esophageal dilatation was grade I in 7 patients and grade II in 22 patients, as defined by the Descriptive Rules for Achalasia of the Esophagus (24). A total of 4 healthy subjects with no severe underlying illnesses were enrolled in the present study (2 male, 2 female; aged 63-68 years). Subsequent to obtaining informed consent, 2 biopsy samples were collected from the middle esophageal mucosa of each patient during esophagoscopy before POEM, and were immediately placed into 1 ml RNAlater reagent (Ambion; Thermo Fisher Scientific, Inc., Waltham, MA, USA) and stored at -80°C for subsequent RNA isolation. All examinations were conducted according to the 6th Good Clinical Practice guidelines and the Declaration of Helsinki, and were approved by the Nagasaki and Showa University Ethics Committees.

POEM. All patients underwent POEM, which was performed as follows and the procedures were performed under general anesthesia with positive pressure ventilation. A submucosal tunnel was formed from the central esophagus to the esophago-gastric junction beyond, using a technique similar to endoscopic mucosal dissection (ESD) (25). An incision was subsequently made of the circular muscle bundle from the entrance to the LES. The incision mucosal invasion was closed with a hemostatic clip (8).

RNA extraction. Total RNA, including small RNA, was extracted from the tissue samples using the mirVana miRNA isolation kit (AM1560; Ambion; Thermo Fisher Scientific, Inc.), and the total RNA was quantified using a Nanodrop-1000 spectrophotometer (Nanodrop Technologies, Wilmington, DE, USA). Next, the total RNA was purified using the miRNeasy mini kit (cat. no. 217004; Qiagen, Hilden, Germany), and the quality of the total RNA was determined by UV absorption measurement and on Agilent 2100 Bioanalyzer (Agilent Technologies, Santa Clara, CA, USA).

miR array hybridization and analysis. In order to identify the miR(s) specific to the esophageal mucosa of achalasia, total RNA was extracted from the biopsy mucosal tissues of 8 representative cases of achalasia and from those of 4 healthy volunteer controls. Following DNase treatment, the isolated RNA samples were subjected to comprehensive analysis of miR expression patterns using microarray-based technology. These analyses were performed by Hokkaido System Science Co., Ltd. (Sapporo, Japan) using the SurePrint G3 Human 8x60 K microarray version 2.0 (Agilent Technologies) and 50 ng aliquots of each total RNA sample. The scan was performed using the Agilent Technologies Microarray Scanner (Agilent Technologies) at 3 μm resolution, and each spot was digitized using Agilent Feature Extraction version 10.7.3.1 software. To identify the miRs that were differentially expressed in esophageal mucosa, data were imported to GeneSpring GX version 10.7.3.1 (Agilent Technologies) and analyzed; a feature is considered detected if the signal is three-fold greater than the error. The differences in miR expression were considered as statistically significant if the

Figure 1. Microarray analysis of miRNA expression in esophageal achalasia patients. The microarray results indicated high expression of miR-361-5p and miR-130a in the esophageal mucosa of esophageal achalasia patients compared with healthy controls. The red and orange colors indicate high expression, bright green indicates low expression.

fold change in expression values was >2.0 and $P < 0.05$ using a Student's t-test.

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR) analysis. The expression levels of miRs that showed significant differences based on the microarray results were analyzed using RT-qPCR. Briefly, cDNA was prepared from total RNA using the High Capacity cDNA Reverse Transcription kit (cat. no. 4374966; Applied Biosystems; Thermo Fisher Scientific, Inc.) and the indicated TaqMan small RNA assay kit (Applied Biosystems; Thermo Fisher Scientific, Inc.). The RT reactions were performed in a solution containing 10 ng total RNA, 1X RT primer, 1X RT buffer, 1 mM dNTP, 50 units MultiScribe Reverse Transcriptase and 3.8 units of RNase inhibitor. Nuclease-free water was added to bring the solution to a total volume of 15 μ l. The reactions were run on the TGradient thermocycler (Biometra GmbH, Göttingen, Germany) at 16°C for 30 min, followed by 42°C for 30 min, and then 85°C for 5 min. Subsequently, qPCR reactions were performed in a solution containing 1.33 μ l RT products with 1X TaqMan Universal Master Mix II without Uracil-N glycosylase (UNG) (cat. no. 4440040; Applied Biosystems; Thermo Fisher Scientific, Inc.) and 1 μ l of each of the TaqMan small RNA assay primers. Each Taqman small RNA primer set contained primers for the analysis of has-miR-361-5p, has-miR-130a and RNU6B (cat. nos. 000554, 000454 and 001093, respectively; Applied Biosystems; Thermo Fisher Scientific, Inc.) Nuclease-free water was added to obtain a solution with total volume of 20 μ l. All reactions were run in triplicate using the LightCycler 480 II (Roche Diagnostics, Basel, Switzerland). The thermal cycling reactions were initiated at 95°C for 10 min, followed by 45 cycles of 95°C for 15 sec, and 60°C for 1 min. The cycle passing threshold (Cq) was recorded for each candidate miR, and the $2^{-\Delta\Delta Cq}$ method was used with RNU6B as the endogenous control for data normalization (12).

In order to determine potential target genes of miR-130a, RT-qPCR was performed to determine changes in the mRNA expression in the mucosa of achalasia patients compared with that in healthy controls. cDNA was prepared from total

RNA using the High Capacity cDNA Reverse Transcription kit (cat. no. 4374966; Applied Biosystems; Thermo Fisher Scientific, Inc.). The RT reactions were performed in a solution containing 500 ng total RNA, 1X Random Primer, 1X RT Buffer, 4 mM dNTP, 50 units MultiScribe Reverse Transcriptase and 20 units RNase Inhibitor. Nuclease-free water was added to obtain a total volume of 20 μ l. The reactions were run on the TGradient thermocycler (Biometra) at 25°C for 10 min, followed by 37°C for 120 min, and 85°C for 5 min. Next, qPCR reactions were performed in a solution containing 4 μ l RT products with 1X TaqMan Universal Master Mix II without UNG (cat. no. 4440040; Applied Biosystems; Thermo Fisher Scientific, Inc.) and 1 μ l of each of the TaqMan mRNA assay primer sets. Nuclease-free water was added to bring the total volume up to 20 μ l. Of the significantly altered genes, *in silico* Target Scan (version 6.2; Whitehead Institute for Biomedical Research, Cambridge, MA, USA) prediction indicated that myotubularin related protein 10 (MTMR10) and WNK lysine deficient protein kinase 1 (WNK1) may be candidate target genes of miR-130a, based on the seed sequence matches in their 3'-UTRs. The TaqMan mRNA primer sets used were for the amplification of the mRNAs for MTMR10, WNK1 and glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (cat. nos. Hs01107504_m1, Hs00219183_m1 and Hs99999905_m1, respectively; Applied Biosystems; Thermo Fisher Scientific, Inc.). Reactions were run on the LightCycler 480 II (Roche Diagnostics), and thermal cycling was initiated at 95°C for 10 min, followed by 45 cycles of 95°C for 15 sec and 60°C for 1 min. Cq values were recorded for each candidate mRNA, and the $2^{-\Delta\Delta Cq}$ method was performed, using GAPDH as the endogenous control for data normalization.

Statistical analysis. The differences between groups were analyzed using the unpaired, one-tailed, Student's t-test. Data are expressed as the mean \pm standard error. Differences were considered to be statistically significant at $P < 0.05$. Multiple regression analyses were also performed. All data were analysed using StatFlex version 6 (Artech Information Systems LLC, Morristown, NJ, USA).

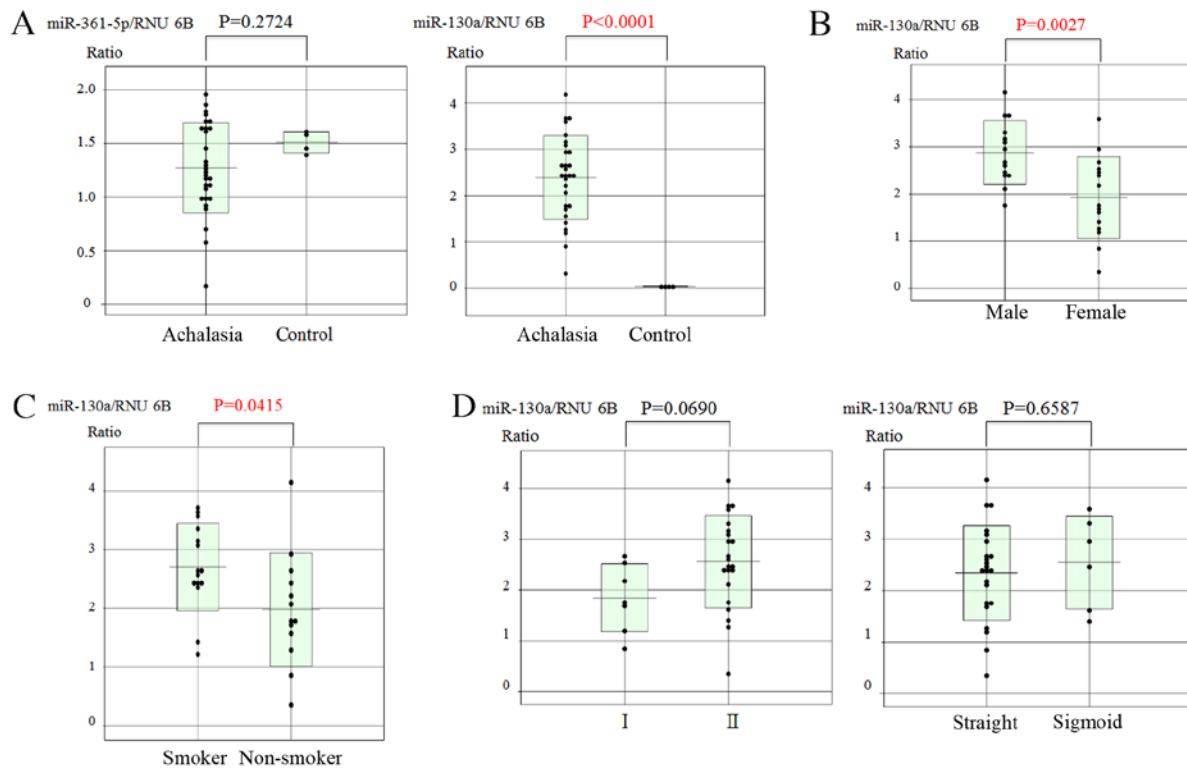

Figure 2. Expression levels of miR-361-5p and miR-130a in achalasia patients, and the association of miR-130a with sex, smoking and esophageal dilation. (A) Quantitative analysis of miR-361-5p and miR-130a expression in achalasia patients and healthy subjects, analyzed using reverse transcription-quantitative polymerase chain reaction. The data are shown relative to RNU6B expression. miR-130a demonstrated a significantly higher expression in achalasia patients vs. control healthy subjects ($P<0.0001$). (B) Significant correlation was observed between the expression of miR-130a and male sex (vs. female sex; $P=0.0027$) in achalasia patients. (C) Significant correlation was detected between the expression of miR-130a and smoking habit (vs. non-smoker; $P=0.0415$) in achalasia patients. (D) No significant correlation was detected between the expression of miR-130a and the type of achalasia or the degree of esophageal dilatation. miR, microRNA.

Results

Patient characteristics. Of the patients enrolled in the present study, 23 suffered from straight-type achalasia and 6 with sigmoid-type achalasia. The degree of esophageal dilatation was grade I in 7 patients and grade II in 22 patients (24). The mean disease duration was 60 months, ranging between 5 and 564 months.

Microarray analysis results. The microarray analysis of miR expression levels in the esophageal mucosa of achalasia indicated that miR-361-5p and miR-130a were significantly (>2 -fold) overexpressed in the esophageal mucosa of achalasia patients when compared with the controls (Fig. 1). Subsequently, RT-qPCR was used to quantify the expression levels of these two miRs in biopsy specimens of achalasia patients and controls. The results revealed that only the expression of miR-130a was significantly higher in achalasia patients compared with that in healthy subjects ($P<0.0001$; Fig. 2A).

Correlation of miR-130a expression with various parameters. The correlation between the miR-130a expression and the background characteristics of the patients was then analyzed. Significant correlations were observed between the expression levels of miR-130a and sex, with males having significantly higher levels than females ($P=0.0027$; Fig. 2B)

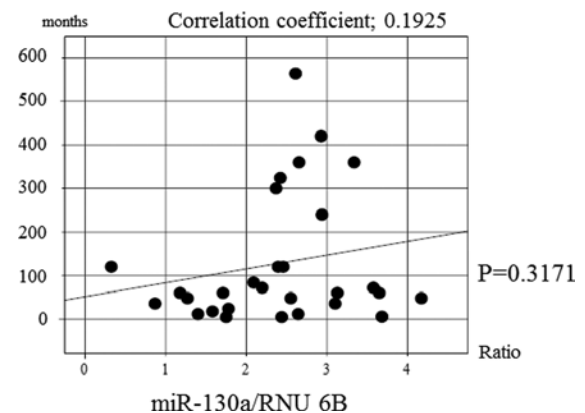

Figure 3. Correlation analysis between miR-130a expression and the disease duration in achalasia patients. The results indicated no significant correlation. miR, microRNA.

and smoker status (elevated in smokers vs. non-smoker; $P=0.0415$; Fig. 2C) in achalasia patients. However, there were no correlations between miR-130a expression and the degree of esophageal dilatation or the type of achalasia (Fig. 2D). In addition, there was no significant correlation between the expression of miR-130a and the disease duration in achalasia patients (Fig. 3). Multiple regression analysis demonstrated that there was a significant correlation between miR-130a expression and smoking ($P=0.0084$; data not shown).

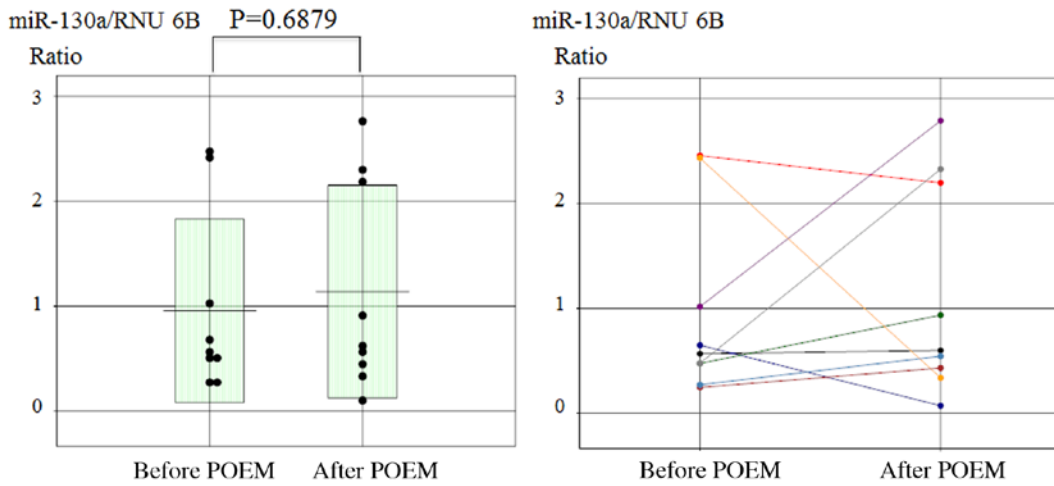

Figure 4. miR-130a expression prior to and following the POEM procedure in achalasia patients analyzed using reverse transcription-quantitative polymerase chain reaction. No significant change was observed in miR-130a expression before and after POEM. miR, microRNA; POEM, peroral endoscopic myotomy.

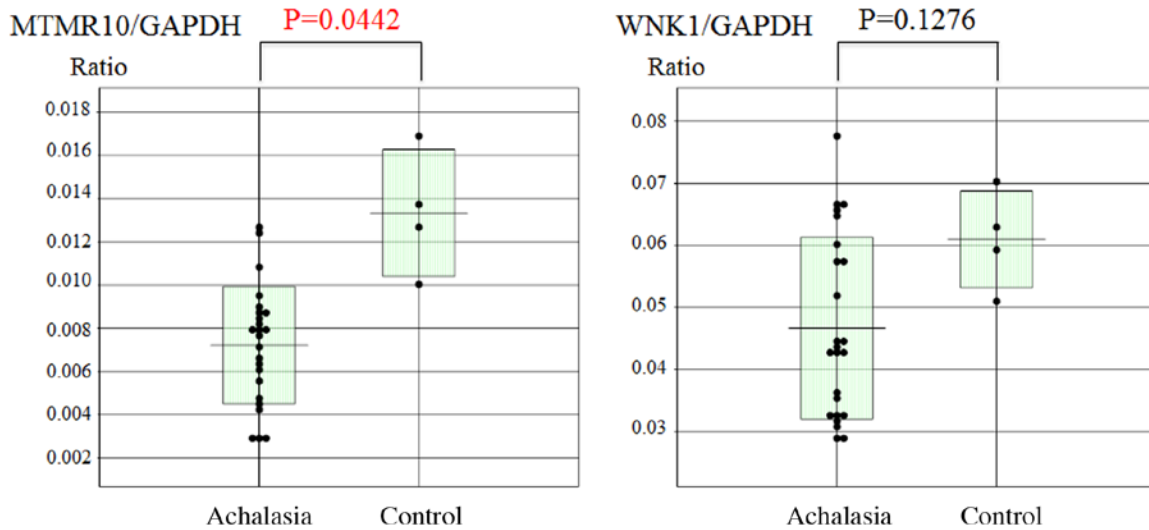

Figure 5. Analysis of the association of mRNA expression levels of MTMR10 and WNK1 with achalasia. A significant correlation with MTMR10 levels was observed in the achalasia patients, as compared with the control group (P=0.0442). MTMR10, myotubularin related protein 10; WNK1, WNK lysine deficient protein kinase 1.

Furthermore, no significant change in miR-130a expression was observed prior to and following the POEM procedure in achalasia patients (Fig. 4).

cDNA array analysis results. In order to determine potential target genes of miR-130a, a cDNA array analysis was performed to determine changes in gene expression in the mucosa tissue of achalasia patients compared with the healthy controls. This analysis indicated that there were 845 genes that were upregulated 1.5-fold and 969 genes that were down-regulated by 1.5-fold in achalasia mucosa compared with the control. The levels of these genes were substantially decreased in achalasia patients according to the results of comprehensive cDNA microarray.

Subsequently, the esophageal mucosal mRNA expression levels of MTMR10 and WNK1 were analyzed using RT-qPCR. The mucosal MTMTR10 mRNA levels, but not WNK1, were

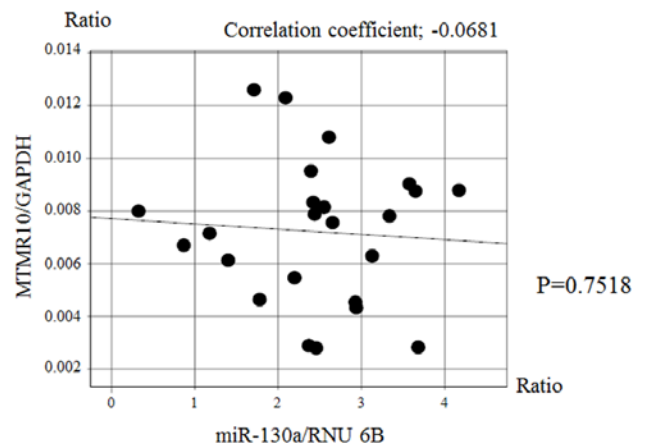

Figure 6. Correlation analysis between the expression of miR-130a and the mRNA expression of MTMR10 indicated no significant correlation. miR, microRNA; MTMR10, myotubularin related protein 10.

significantly decreased in achalasia patients compared with those in the controls ($P=0.0442$; Fig. 5). However, there was no significant correlation between the expression of miR-130a and that of MTMR10 (Fig. 6).

Discussion

The present study demonstrated that miR-130a was highly expressed in the esophageal mucosa of achalasia patients and that smoking history was associated with a high expression of miR-130a. The miR-130a gene is located at the chromosomal position 11q12, which is close to the region 11q13 that is frequently amplified in cancer (26-29). In fact, miR-130a serves an important role in multiple types of tumors. For instance, miR-130a has been reported to be overexpressed in non-small-cell lung carcinoma (30). Increased expression of miR-130a is strongly associated with lymph node metastasis and poor prognosis of this carcinoma (30). By contrast, miR-130a is downregulated in prostate carcinomas and jointly suppresses two major oncogenic pathways with miR-203 and miR-205 (31). miR-130a also increases drug resistance by regulating RUNX3 and Wnt signaling in cisplatin-treated hepatocellular carcinoma cells (32), while upregulation of miR-130a has been associated with MDR1/P-glycoprotein-mediated drug resistance in ovarian cancer cells (33). Acunzo *et al* (34) reported that miR-130a was able to target Met and induce TNF-related apoptosis-inducing ligand sensitivity in non-small-cell lung carcinomas by downregulating miR-221 and miR-222.

In the current study, no significant change in miR-130a expression was observed between before and after POEM. Although POEM may be one option to reduce patient suffering and decrease the risk of future carcinogenesis (8), it is unable to completely prevent achalasia patients from developing esophageal cancer. Several studies have reported the association of smoking with miRs, as well as with lung diseases (35) and various types of cancer (36), including esophageal cancer (12). In the present study, the results suggested that smoking history may be associated with the expression level of miR-130a. However, we were unable to compare the expression of miR-130a in healthy non-smokers, healthy smokers, achalasia non-smokers and achalasia smokers in the current study, and therefore further studies are warranted.

The myotubularin gene (MTM1) was identified as a gene mutated in X-linked myotubular myopathy (37). A subgroup of genes in the myotubularin family encodes proteins that contain substitutions of residues within the C(X)₅R active site motif and are catalytically inactive. Of the 14 known MTM related (MTMR) human genes, 6 (MTMR5, MTMR9, MTMR10, MTMR11, MTMR12 and MTMR13) encode inactive proteins, whereas the function of MTMR10 is largely unknown (38). In the current study, miR-130a and MTMR10 expression were not correlated at the mRNA level; however, it is possible that they are associated at the protein level. However, the association between esophageal achalasia and MTMR10 remains unclear, thus further studies are also warranted in this regard.

In conclusion, miR-130a is highly expressed in the esophageal mucosa of esophageal achalasia. Furthermore, smoking history may be associated with the expression level of miR-130a. Therefore, miR-130a may be a useful mucosal biomarker of esophageal achalasia.
