# Effects of d-Leu Residues on the Helical Secondary Structures of l-Leu-Based Nonapeptides 

Yosuke Demizu, ${ }^{*, a}$ Hiroko Yamashita, ${ }^{a, b}$ Takashi Misawa, ${ }^{a}$ Mitsunobu Doi, ${ }^{c}$ Masakazu Tanaka, ${ }^{d}$ and Masaaki Kurihara* ${ }^{*}, b$<br>${ }^{a}$ Division of Organic Chemistry, National Institute of Health Sciences; 1-18-1 Kamiyoga, Setagaya, Tokyo 158-8501, Japan: ${ }^{b}$ Graduate School of Bioscience and Biotechnology, Tokyo Institute of Technology; Yokohama 226-8501, Japan: ${ }^{\text {c }}$ Osaka University of Pharmaceutical Sciences; Osaka 569-1094, Japan: and ${ }^{d}$ Graduate School of Biomedical Sciences, Nagasaki University; 1-14 Bunkyo-machi, Nagasaki 852-8521, Japan.<br>Received November 5, 2014; accepted December 8, 2014

The influence of d -Leu residues on the helical structures of L -Leu-based-nonapeptides was investigated. Specifically, the preferred conformations of four diastereomeric nonapeptides, Boc-(L-Leu-L-Leu-Aib) ${ }_{3}$-OMe (1); Boc-(L-Leu-L-Leu-Aib) $)_{2}$-L-Leu-d-Leu-Aib-OMe (2), which contained one d-Leu residue; Boc-l-Leu-d-Leu-Aib-L-Leu-L-Leu-Aib-L-Leu-d-Leu-Aib-OMe (3), which contained two d-Leu residues; and Boc-(L-Leu-d-Leu-Aib) $)_{3}$-OMe (4), were analyzed in solution and in the crystalline state. Peptide 1 formed a righthanded $(P) 3_{10}$-helix in solution. Peptides 2 and 3 both formed $(P) 3_{10}$-helices in solution and $(P) a$-helices in the crystalline state. Peptide 4 formed a $(P) \alpha$-helix both in solution and in the crystalline state.

Key words $\alpha$-aminoisobutyric acid; peptide; conformation; helical structure

Helices are present throughout nature and play important roles in many daily functions. In the human body, microhelices are ubiquitous, e.g., they are found in DNA and protein molecules, and the helices in proteins play important roles in the recognition of biomolecules such as DNA, RNA, and other proteins. Therefore, the de novo design of peptides that fold into well-defined helical structures has been attracted great interest of many chemists. Non-proteinogenic amino acids such as $\alpha, \alpha$-disubstituted $\alpha$-amino acids, ${ }^{1-4)}$ cyclic $\beta$-amino acids, ${ }^{5-9)}$ and cross-linked side chains ${ }^{10,11)}$ are often utilized as tools for peptide-helix stabilization. In particular, $\alpha$-aminoisobutyric acid (Aib) has been widely incorporated into short natural l-peptides to promote the formation and the stabilization of helical structures. ${ }^{12)}$ Recently, we have reported that the introduction of Aib residues into the leucine (Leu)-based Lpeptide stabilized its right-handed $(P) 3_{10}$-helix Boc-(L-Leu-

L-Leu-Aib) $)_{3}$-OMe (1), ${ }^{13)}$ whereas the insertion of achiral Aib residues into alternating Leu-based LD-peptides stabilized their $\alpha$-helices, but not their $3_{10}$-helices. Specifically, we reported that the nonapeptide Boc-(L-Leu-d-Leu-Aib) $)_{3}-\mathrm{OMe}$ (4) formed a ( $P$ ) $\alpha$-helix both in solution and in the crystalline state. ${ }^{14,15)}$ As part of our ongoing research, we investigated the influence of D-Leu residues on the helical structures of L-Leu-based nonapeptides. We designed and synthesized four diastereomeric nonapeptides, Boc-(L-Leu-L-Leu-Aib) $3_{3}$-OMe (1), ${ }^{13)}$ Boc-(L-Leu-L-Leu-Aib) ${ }_{2}$-L-Leu-d-Leu-Aib-OMe (2), which contained one d-Leu residue, Boc-L-Leu-d-Leu-Aib-L-Leu-L-Leu-Aib-L-Leu-D-Leu-Aib-OMe (3), which contained two D-Leu residues, and Boc-(L-Leu-d-Leu-Aib) ${ }_{3}-\mathrm{OMe}$ (4), ${ }^{14}$ which contained equal amounts of L-Leu and D-Leu residues, and then analyzed their preferred conformations in solution and in the crystalline state (Fig. 1).

## Results and Discussion

Synthesis of Peptides The peptides 1 and 4 were synthesized in accordance with the methods outlined in refs. 13 and 14 , respectively. The nonapeptides Boc-(L-Leu-L-Leu-Aib) $2^{-}$ l-Leu-d-Leu-Aib-OMe (2) and Boc-L-Leu-d-Leu-Aib-L-Leu-L-Leu-Aib-L-Leu-d-Leu-Aib-OMe (3) were synthesized using conventional solution-phase methods involving a fragment condensation strategy in which 1-(3-dimethylaminopropyl)-3-ethylcarbodiimide (EDC) hydrochloride and 1-hydroxybenzotriazole (HOBt) hydrate were employed as coupling reagents. All of the compounds were purified by column chromatography on silica gel.

Conformational Analyses of the Peptides in Solution (Fourier Transform (FT)-IR and Circular Dichroism (CD)

Spectra) The IR spectra of peptides 2, $\mathbf{3}$ and 4 were measured in the NH-stretching region $\left(3200-3500 \mathrm{~cm}^{-1}\right)$ at a peptide concentration of 2.0 mm in $\mathrm{CDCl}_{3}$ solution. In the spectra of $\mathbf{2}, \mathbf{3}$ and $\mathbf{4}$, the weak bands in the 3434 and $3439 \mathrm{~cm}^{-1}$ regions were assigned to solvated free peptide NH groups, and the strong band at $3334 \mathrm{~cm}^{-1}$ was assigned to peptide NH groups with $\mathrm{N}-\mathrm{H} \cdots \mathrm{O}=\mathrm{C}$ intramolecular H -bonds. These spectra were very similar to those of helical peptides in solution. ${ }^{3,16)}$ Peptide 1 exhibited similar spectra to peptides 2, $\mathbf{3}$ and $4^{13)}$ (Fig. 2).
The CD spectra of peptides $\mathbf{1 - 4}$ were measured in 2,2,2-trifluoroethanol (TFE) and TFE and phosphate buffered saline (PBS) buffer ( $1: 1$ ) solution (peptide concentration: 0.1 mm ). The spectra of the peptides displayed negative maxima at

around 206 and 224 nm ( 208 nm and 224 nm for the peptide 4), indicating that they possessed a right-handed $(P)$ helical screw sense, as shown in Fig. 3A. ${ }^{12)}$ Based on the $R$ values ( $\theta_{224} / \theta_{206}$ ) of the peptides, the homochiral peptide $\mathbf{1}$ and the heterochiral peptides 2 and $\mathbf{3}$ formed $3_{10}$-helices as their dominant conformations ( $R=0.38$ for $\mathbf{1}, R=0.44$ for $\mathbf{2}, R=0.34$ for $\mathbf{3}$ ), whereas the LD-peptide 4 preferentially formed an $\alpha$-helix ( $R=\theta_{224} /$ $\left.\theta_{209}=0.71\right) .{ }^{17)}$ Based on the intensity values of the peptides' CD spectra, it was considered that peptide $\mathbf{1}$, which is entirely composed of L -Leu residues, formed the most right-handed $(P)$ helical structure, and the peptides' CD intensities decreased linearly as the number of D -Leu residues in the nonapeptide sequence increased. Whereas, the peptide 4 having the alternating $\mathrm{L}-$ Leu-d-Leu-Aib segment preferentially formed a right-handed ( $P$ ) $\alpha$-helix rather than a $3_{10}$-helix. ${ }^{15)}$ Thus, as the number of d -Leu residues in a helical L-peptide sequence increased, the right-handed $(P) 3_{10}$-helices are gradually destabilized and tends to change their dominant conformations from $3_{10}$-helices to $\alpha$-helices. Even in a mixture of TFE and PBS buffer ( $1: 1$ ) solution, all peptides formed $(P)$ helical structures, respectively, as shown in Fig. 3B.
X-Ray Diffraction Analysis Peptides 2 and 3 produced suitable crystals for X-ray crystallographic analysis after the slow evaporation of $\mathrm{N}, \mathrm{N}$-dimethylacetamide (DMA) $/ \mathrm{H}_{2} \mathrm{O}$ and $\mathrm{MeOH} / \mathrm{MeCN}$, respectively, at room temperature. The crys-

tal and diffraction parameters of $\mathbf{2}$ and $\mathbf{3}$ are summarized in Table 1. Data collection was performed using a Bruker AXS SMART APEX imaging plate diffractometer and graphitemonochromated $\mathrm{Mo} K \alpha$ radiation. The structures of 2 and 3 were solved by the direct method using SHELXS $97^{18)}$ and expanded using the Fourier technique. ${ }^{19)}$ All non-H atoms were given anisotropic thermal parameters, some H atoms were refined isotropically, and the remaining H atoms were placed at the calculated positions. ${ }^{20)}$ The crystal and diffraction parameters of the peptides, as well as relevant backbone and side chain torsion angles and intra- and intermolecular hydrogenbond parameters are summarized in Tables 2 and 3.

A right-handed $(P) \alpha$-helix with a dimethylacetamide molecule was existed in the asymmetric unit of Boc-(L-Leu-L-Leu-Aib) $)_{2}$-L-Leu-d-Leu-Aib-OMe (2) (Fig. 4). The mean $\varphi$ and $\psi$ torsion angles of the amino acid residues (1-6) were $-59.1^{\circ}$ and $-40.2^{\circ}$, respectively, which are close to those of an ideal ( $P$ ) $\alpha$-helix ( $-60^{\circ}$ and $-45^{\circ}$, respectively). However, the D-Leu (8) residue was flipped, ${ }^{21,22)}$ and its $\varphi$ and $\psi$ torsion angles were positive $\left(\varphi=+92.3^{\circ}, \psi=+11.9^{\circ}\right)$. Two $i \leftarrow i+3$ type, two $i \leftarrow i+4$ type, and one $i \leftarrow i+5$ type hydrogen bond were found in the $\alpha$-helix of 2. Hydrogen bonds were detected between the $\mathrm{H}-\mathrm{N}(4)$ and $\mathrm{C}(0)=\mathrm{O}(1)[\mathrm{N}(4) \cdots \mathrm{O}(0)=3.47 \AA$; a bit long for a hydrogen bond], between the $\mathrm{H}-\mathrm{N}(5)$ and $\mathrm{C}(1)=\mathrm{O}(1)$ $[\mathrm{N}(5) \cdots \mathrm{O}(1)=2.91 \AA]$, between the $\mathrm{H}-\mathrm{N}(6)$ and $\mathrm{C}(2)=\mathrm{O}(2)$ $[\mathrm{N}(6) \cdots \mathrm{O}(2)=3.20 \AA]$, between the $\mathrm{H}-\mathrm{N}(7)$ and $\mathrm{C}(4)=\mathrm{O}(4)$ $[\mathrm{N}(7) \cdots \mathrm{O}(4)=3.01 \AA]$, between the $\mathrm{H}-\mathrm{N}(8)$ and $\mathrm{C}(5)=\mathrm{O}(5)$ $[\mathrm{N}(8) \cdots \mathrm{O}(5)=2.89 \AA]$, and between the $\mathrm{H}-\mathrm{N}(9)$ and $\mathrm{C}(4)=\mathrm{O}(4)$
$[\mathrm{N}(9) \cdots \mathrm{O}(4)=3.01 \AA]$. In packing mode, successive helical molecules were connected by an intermolecular hydrogen bond to form head-to-tail aligned chains.
The asymmetric unit of Boc-L-Leu-d-Leu-Aib-L-Leu-L-Leu-Aib-L-Leu-D-Leu-Aib-OMe (3) contained two righthanded ( $P$ ) $\alpha$-helical structures, in which the d-Leu (8) residue was flipped (Fig. 5). The conformations of molecules $\mathbf{A}$ and B were well matched, except for small differences in the conformations of their side chains and C-terminus peptide backbones (Fig. 6). The mean $\varphi$ and $\psi$ torsion angles of the $\alpha$-helical residues (1-7) were $-59.3^{\circ}$ and $-42.9^{\circ}$, respectively, for $\mathbf{A}$, and $-59.9^{\circ}$ and $-44.0^{\circ}$, respectively, for B. Regarding the intramolecular H -bonds in molecule $\mathbf{A}$, one $i \leftarrow i+3$ type, four $i \leftarrow i+4$ type, and one $i \leftarrow i+5$ type hydrogen bond were formed. The hydrogen bonds were located between the H $\mathrm{N}(4 \mathrm{a})$ and $\mathrm{C}(0 \mathrm{a})=\mathrm{O}(0 \mathrm{a})[\mathrm{N}(4 \mathrm{a}) \cdots \mathrm{O}(0 \mathrm{a})=3.14 \AA]$, between the $\mathrm{H}-\mathrm{N}(5 \mathrm{a})$ and $\mathrm{C}(1 \mathrm{a})=\mathrm{O}(1 \mathrm{a})[\mathrm{N}(5 \mathrm{a}) \cdots \mathrm{O}(1 \mathrm{a})=2.89 \AA]$, between the $\mathrm{H}-\mathrm{N}(6 \mathrm{a})$ and $\mathrm{C}(2 \mathrm{a})=\mathrm{O}(2 \mathrm{a}) \quad[\mathrm{N}(6 \mathrm{a}) \cdots \mathrm{O}(2 \mathrm{a})=3.09 \AA]$, between the $\mathrm{H}-\mathrm{N}(7 \mathrm{a})$ and $\mathrm{C}(3 \mathrm{a})=\mathrm{O}(3 \mathrm{a})[\mathrm{N}(7 \mathrm{a}) \cdots \mathrm{O}(3 \mathrm{a})=3.18 \AA]$, between the $\mathrm{H}-\mathrm{N}(8 \mathrm{a})$ and $\mathrm{C}(5 \mathrm{a})=\mathrm{O}(5 \mathrm{a})[\mathrm{N}(8 \mathrm{a}) \cdots \mathrm{O}(5 \mathrm{a})=2.94 \AA]$, and between the $\mathrm{H}-\mathrm{N}(9 \mathrm{a})$ and $\mathrm{C}(4 \mathrm{a})=\mathrm{O}(4 \mathrm{a})[\mathrm{N}(9 \mathrm{a}) \cdots \mathrm{O}(4 \mathrm{a})=2.93 \AA]$. In molecule $\mathbf{B}$, the same types of H -bonds as shown in molecule $\mathbf{A}$, were detected between the $\mathrm{H}-\mathrm{N}(4 \mathrm{~b})$ and $\mathrm{C}(0 \mathrm{~b})=\mathrm{O}(0 \mathrm{~b}) \quad[\mathrm{N}(4 \mathrm{~b}) \cdots \mathrm{O}(0 \mathrm{~b})=3.25 \AA]$, between the $\mathrm{H}-\mathrm{N}(5 \mathrm{~b})$ and $\mathrm{C}(1 \mathrm{~b})=\mathrm{O}(1 \mathrm{~b})[\mathrm{N}(5 \mathrm{~b}) \cdots \mathrm{O}(1 \mathrm{~b})=2.95 \AA]$, between the $\mathrm{H}-$ $\mathrm{N}(6 \mathrm{~b})$ and $\mathrm{C}(2 \mathrm{~b})=\mathrm{O}(2 \mathrm{~b}) \quad[\mathrm{N}(6 \mathrm{~b}) \cdots \mathrm{O}(2 \mathrm{~b})=3.02 \AA]$, between the $\mathrm{H}-\mathrm{N}(7 \mathrm{~b})$ and $\mathrm{C}(3 \mathrm{~b})=\mathrm{O}(3 \mathrm{~b}) \quad[\mathrm{N}(7 \mathrm{~b}) \cdots \mathrm{O}(3 \mathrm{~b})=3.31 \AA$; a bit long for a H-bond], between the $\mathrm{H}-\mathrm{N}(8 \mathrm{~b})$ and $\mathrm{C}(5 \mathrm{~b})=\mathrm{O}(5 \mathrm{~b})$

In packing mode, molecules $\mathbf{A}$ and $\mathbf{B}$ were alternately connected by intermolecular hydrogen bonds.

## Conclusion

Four diastereomeric nonapeptides, Boc-(L-Leu-L-Leu-Aib) $3^{-}$ OMe (1), ${ }^{13)} \quad$ Boc-(L-Leu-L-Leu-Aib) ${ }_{2}$-L-Leu-d-Leu-Aib-OMe (2), Boc-L-Leu-d-Leu-Aib-L-Leu-L-Leu-Aib-L-Leu-d-Leu-AibOMe (3), and Boc-(L-Leu-d-Leu-Aib) ${ }_{3}$-OMe (4), ${ }^{14)}$ were synthesized to investigate the influence of D -Leu residues on the helical structures of $\mathrm{L}-\mathrm{Leu}$-based nonapeptides. In solution, the homochiral peptide $\mathbf{1}$, which only contained l-Leu residues, formed the most righ-handed $(P)$ helical structure. Increasing the number of D-Leu residues in the L-Leu-based nonapeptide sequence decreased the right-handedness of the resultant helical peptides. Peptides 1, 2, and 3 formed $3_{10}$-helices as their dominant conformations, whereas the dominant conformation of peptide 4, which contained alternating l-Leu-d-Leu fragments, was an $\alpha$-helix. In short peptide sequences, Aib residues are able to stabilize $3_{10}$-helices, but not $\alpha$-helices, and therefore, peptides $\mathbf{1}, \mathbf{2}$, and $\mathbf{3}$ formed $3_{10}$-helices in solution. On the other hand, peptide 4 , which was composed of the well-regulated $\mathrm{l}-$ Leu-d-Leu-Aib segment, formed a righthanded $(P) \alpha$-helix rather than a $3_{10}$-helix. ${ }^{15)}$

In the crystalline state, peptide 2 , which contained one D-Leu residue, and peptide 3, which contained two d-Leu residues, were folded into $(P) \alpha$-helices with flipped C-terminal d-Leu (8) residues. In packing mode, peptides 3 and 4 probably tend to form $\alpha$-helices, rather than $3_{10}$-helices, in order to avoid amino acid side-chain competition between the $i$ and $i+3$ positions. The incorporation of increasing numbers of D-Leu residues into L-Leu-based helical nonapeptides gradually destabilizes the right-handedness of their helices and tends to change their dominant conformations from $3_{10}$-helices to $\alpha$-helices. These findings could have important implications for the construction of well-defined short helical peptides.

## Experimental

General Optical rotation $[\alpha]_{\mathrm{D}}$ was assessed using a 1.0 dm cell in MeOH. ${ }^{1} \mathrm{H}$ - and ${ }^{13} \mathrm{C}-\mathrm{NMR}$ spectra were recorded at 400 MHz and 100 MHz in $\mathrm{CDCl}_{3}$ using tetramethylsilane as an internal standard. Fourier transform infrared (FT-IR) spectra were recorded on a JASCO FT/IR-4100 spectrometer at a resolution of $1 \mathrm{~cm}^{-1}$ over a mean of 128 scans using the solution $\left(\mathrm{CDCl}_{3}\right)$ method and NaCl cells with a path length of 0.1 mm . CD spectra were recorded with a JASCO J-720W spectropolarimeter using a cell with a $1.0-\mathrm{mm}$ path length. The resultant data are expressed in terms of $[\theta]_{\mathrm{R}}$, the total molar ellipticity ( $\operatorname{deg} \mathrm{cm}^{2} \mathrm{dmol}^{-1}$ ). 2,2,2-Trifluoroethanol (TFE) and a mixture of TFE/PBS ( $1: 1$ ) solution were used as a solvent. The data collection for the X-ray diffraction analysis was performed on Rigaku RAXIS-RAPID and Bruker AXS SMART APEX imaging plate diffractometers using graphitemonochromated MoK radiation.
