Efficient Method for Selective Oxidation of 1,2-Diols in Water Catalyzed by Me₂SnCl₂

Julius M. William,^a Masami Kuriyama,^a and Osamu Onomura^{*a}

Received (in XXX, XXX) Xth XXXXXXXX 20XX, Accepted Xth XXXXXXXX 20XX 5 DOI: 10.1039/b000000

Dimethyltin(IV)dichloride-catalyzed selective oxidation of 1,2diols in water was achieved using dibromoisocyanuric acid (DBI) or Br₂ as oxidants. The catalyst activates the 1,2-diol moiety ¹⁰ through the formation of stannylene acetal in addition to enhancing selectivity. Various cyclic and acyclic 1,2-diols substrates have been selectively oxidized affording α hydroxyketones in good to excellent yields. This method is safe and simple in operation.

15

Introduction

Organic reactions in water as a solvent or co-solvent have 20 attracted a lot of attention recently. This is because of the unique properties of water and its key role as a solvent for green chemistry.¹ With increasing regulatory pressure targeting organic solvents, the development of nonhazardous alternatives is of great importance.² Selective oxidation of 1,2-diols to their 25 corresponding a-hydroxyketones is a basic and an important organic reaction.³ This is because α -hydroxyketones unit is found in some antitumor antibiotics and important natural products like olivomycin A,⁴ kurasoin A and B.⁵ However, the few methods available for selective oxidation of 1,2-diols to α -30 hydroxyketones,⁶⁻¹¹ suffer drawbacks such as relatively low yields and side reactions accompanying C-C bond cleavage.¹⁰ Use of Bu₂SnO,¹² has been recognized as a highly selective method. It proceeds in two stages: formation of stannylene acetal **b** by azeotropic condensation of 1,2-diol **1** with Bu₂SnO followed

³⁵ by the oxidation of **b** by Br₂ (Scheme1).

 $\begin{array}{c} R^{1} \longrightarrow OH \\ R^{2} \longrightarrow OH \\ 1 \end{array} \xrightarrow{(nBu)_{2}Sn=O} \\ R^{2} \longrightarrow O' \\ R^{2} \longrightarrow O' \\ B \\ Stannylene acetal \end{array} \xrightarrow{Br_{2}} \\ R^{1} \longrightarrow O' \\ R^{2} \longrightarrow O' \\ R^{2$

Scheme 1 Oxidation of 1,2-diols via stannylene acetal.

This method has been applied to the synthesis of (+)spectinomycin¹³ and to the oxidation of sugars into oxo-sugars.¹⁴ ⁴⁰ Unfortunately, it is unfavourable from environmental viewpoint and also requires more than 1 equimolar amount of Bu₂SnO. So far, a handful of methods on selective oxidation of 1,2-diols in organic solvents have been presented using organotin catalysts, ¹⁵ chiral copper compounds,¹⁶ and electrochemical methods.^{15,17} But ⁴⁵ to the best of our knowledge no report on selective oxidation in

This journal is © The Royal Society of Chemistry [year]

water has been presented. Our most recent report on selective monobenzoylation of 1,2-diols in water,¹⁸ and other reports on selective monobenzoylation in organic solvents,¹⁹ greatly motivated this investigation. In these reports, Me₂SnCl₂ catalyst ⁵⁰ activates the 1,2-diol moiety through the formation of stannylene acetal and also facilitate selectivity. We envisioned that if we introduce a suitable oxidizing agent to a stannylene acetal in water, then selective oxidation may be achieved.

55 Results and discussion

We began our investigation on catalytic selective oxidation of 1,2-diols in water using *cis*-cyclooctane-1,2-diol **1a** as a model substrate and halogen cation "source" oxidants. After a series of optimization studies, we found that monoselective oxidation of **1a** proceeded efficiently in the presence of 10 mol % of Me₂SnCl₂, 1.2 equiv of potassium carbonate, and 1.5 equiv of Br₂ in water at low temperature (0 °C) under shielding the light for 1 h to afford **2a** in (85%) yield (entry1, Table1).

Table 1 Selective oxidation of 1,2-diol 1a in water using various oxidants.

^a Isolated yield. ^b Dibromoisocyanuric acid. ^c 1,3-Dibromo-5,5dimethylhydantoin.^d 1,3-diiodo-5,5-dimethylhyndantoin. Temperature optimization experiments revealed that -5 °C was the optimum temperature for oxidation of **1a** using Br₂, affording (91%) yield (entry 1–3). Reducing the amount of Br₂ to 1.0 equiv led to a drop in yield (78%) (entry 4). Commonly known mild

- ⁵ oxidizing agents, *N*-bromosuccinimide (NBS) and *N*iodosuccinimide (NIS) afforded lower yields at 0 °C (entries 5 and 6), while *N*-chlorosuccinimide (NCS) only afforded a trace amount of the desired product (entry 7). Dibromoisocyanuric acid (DBI), first reported by Gottardi²⁰ as a mild but more effective
- ¹⁰ brominating agent than NBS,²¹ afforded the desired product in an excellent yield of 90% with 1 equiv (entry 8). Increasing the amount of DBI to 1.5 equiv led to the formation of some diketone product resulting in a drop in yield of the desired product (entry 9).
 1.5 Equiv of 1,3-dibromo-5,5-dimethylhydantoin (DBDMH)
 ¹⁵ gave comparable results. However, a closely related 1,3-diiodo-5,5-dimethylhydantoin (DIDMH) was not efficient in effecting this oxidation (entries 10 and 11). Efforts to use H₂O₂ as oxidant

failed as it did not oxidize our reaction. We next investigated the effect of a number of different ²⁰ reaction parameters on the efficiency of selective oxidation of 1,2-diol **1a** in water with Br₂ or DBI. The results are summarized in Table 2.

Table 2 Selective oxidation study by varying various parameters.

²⁵ ^a Isolated yield. ^b 1.5 Equiv of Br₂ was used. ^c 1.0 Equiv of DBI was used.

With bromine as the oxidant, the 90% yield was maintained under oxygen atmosphere, while in argon there was a drop to 73% (entries 1 and 2). Reducing the catalyst loading to 0.05 eqiuv and 0.01 equiv led to drop in yields (entries 3 and 4). As ³⁰ expected, poor yield was obtained in the absence of the catalyst (entry 5). Extending the reaction time to 5 h in the absence of Me₂SnCl₂, resulted in the formation of the diketone and associated drop in the yield of the monoketone (entry 6). Similarly, absence of the base (potassium carbonate) or ³⁵ performing the reaction in presence of light led to drop in yields (entries 7 and 8). In the reaction with DBI as the oxidant but without the catalyst, essentially no reaction was observed (entry 9). As with bromine as the oxidant, reducing the catalyst loading to 0.05 equiv, also led to a drop in yield (76%) (entry 10). ⁴⁰ Similarly, the yield dropped in the absence of the base (entry 11).

Lack of reaction with DBI in the absence of Me₂SnCl₂ prompted us to study the effects of other organotin compounds as potential catalysts in reactions involving different 1,2-diols with 1.0 equiv of this oxidant. The results are summarized in Table 3. ⁴⁵ Me₂SnBr₂ was found to be effective as a catalyst in place of Me₂SnCl₂, although at the expense of slight erosion in selectivity (entry 1). Dialkyltin dichloride catalysts gave moderate yields of mono-oxidation products (entries 2–4), while dialkyltin oxide and Cu salts did not show impressive activities (entries 5–7 and 8–9).

^a Isolated yield.

We next explored the substrate applicability to the oxidation system involving Me₂SnCl₂ as the catalyst and Br₂ or DBI as the 55 oxidants. Generally, selective oxidation using 1.5 equiv of Br₂ and 1.0 equiv DBI gave comparable yields for all substrates screened (Table 4). All meso- and trans-cyclic-1,2-diols, underwent selective oxidation affording mono-oxidized products in moderate to excellent yields (entries 1-6). A number of 60 acyclic-1,2-diols were selectively oxidized at elevated temperature of 50 °C,²² affording corresponding α -hydroxyketones in excellent to moderate yields (entries 7-9). Next, we carried out selective oxidation of 1,2-diols having both primary and secondary alcohols. When 1,2-diols 1k, 1l, 1m, 1n, and 1o 65 were treated under these catalytic conditions, the secondary alcohols were selectively oxidized preferentially affording products 2k, 2l, 2m, 2n, and 2o respectively in moderate to excellent yields (entries 10-14). Additionally, 1,2,6-hexanetriol 1p underwent selective oxidation at the secondary hydroxyl 70 group of the 1,2-diol moiety affording 2p in good yield (entry 15).

Competitive reaction between 1,2-diol **1a** and mono-ol **1q** was next tried (Scheme 2). In the presence of Me₂SnCl₂, **1a** and **1q** were oxidized to **2a** and **2q** in the ratio of 74:26 respectively. On the other hand, in the absence of Me₂SnCl₂, **2q** was 75 predominantly obtained. These results clearly demonstrate the role of Me₂SnCl₂ in the activation of the hydroxyl groups of 1,2diols and the versatility of the DBI as a promising oxidant for mono-ols in water.

Scheme 2 Competition reaction between *cis*-1,2-cyclooctanediol and cyclooctanol.

Table 4 Scope of substrates with Br2 or DBI as oxidants.

^a Isolated yield.

Finally a proposed reaction pathway for selective oxidation of 1,2-diols 1 is shown in Scheme 3. Chelate complex A^{23} formed from the interaction of 1 with Me₂SnCl₂ or related complex A' ¹⁰ (activated intermediates), could be oxidized by (Br⁺) generated

from the oxidant in water leading to 2.

15 Conclusions

A catalytic process for selective oxidation of 1,2-diols in water under mild conditions has been achieved. This method not only provides a new approach to an environmentally benign process for selective oxidation 1,2-diols but also introduces an efficient ²⁰ oxidant (DBI) with superior results compared to NBS, which has commonly been used for selective oxidation in organic solvents. The method may also have potential in selective oxidation of specific hydroxyl groups in polyols. Selective oxidation using more safer catalysts and enantioselective oxidation of 1,2-diols in ²⁵ water is currently ongoing in our lab.
